1.0 INTRODUCTION

Environmental monitoring programs at the Rocky Flats Environmental Technology Site (RFETS or the Site) continue to evolve in response to new regulatory drivers and accelerated Site closure. Various monitoring programs have amassed data on soils, surface water, groundwater, air, and different ecological systems. The *Rocky Flats Cleanup Agreement* (RFCA) (DOE et al., 1996) requires U.S. Department of Energy (DOE), in consultation with the Colorado Department of Public Health and Environment (CDPHE) and the U.S. Environmental Protection Agency (EPA), to establish an Integrated Monitoring Program that effectively collects and reports the data required to ensure the protection of human health and the environment. The program is consistent with the RFCA Preamble, and complies with RFCA itself, laws and regulations, and effective management of RFETS's resources. The *Integrated Monitoring Plan* (IMP) [Kaiser-Hill Company, L.L.C. (Kaiser-Hill), 1997a] identifies the routine monitoring programs for surface water, groundwater, air, and ecology designed to minimize duplication of efforts among DOE, CDPHE, the cities of Broomfield and Westminster, and associated data management systems. Specific Site activities involve soil monitoring, but Site-wide soil monitoring was discontinued in 1994, after many years of characterizing transuranic-contaminant distributions across the Site.

The IMP captures the Site monitoring performed for a variety of legal, contractual, and operational purposes and restates the agreed-upon types of monitoring, monitoring locations, sampling frequencies, and purposes of the monitoring to meet the RFCA goal. In some instances, the IMP captures monitoring that is already legally required outside of RFCA. Where this is the case, such monitoring requirements are not subject to enforcement pursuant to RFCA, but may be subject to enforcement in accordance with the initiating legal requirements. In addition, the Site's monitoring programs encompass Best Management Practices (BMPs) that are not required by RFCA or other federal and state laws and regulations. The BMPs are incorporated into the IMP but may be dependent on the availability of federal funding in accordance with RFCA, Paragraph 249. The *IMP Background Document* (Kaiser-Hill, 1998) is not subject to enforcement under RFCA.

In developing the Integrated Monitoring Program, Site personnel met with a working group of representatives from EPA, the State of Colorado, and the cities of Westminster, Northglenn, Thornton, Arvada, and Broomfield to develop consensus on the types of data to be gathered and their eventual uses (the data quality objectives, or DQOs, described below). The program is designed to provide data that meet the DQOs by supporting operational and regulatory decisions, and address the following primary regulatory drivers:

- The Resource Conservation and Recovery Act (RCRA),
- The Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA),
- The Clean Air Act (CAA),
- The Clean Water Act (CWA),
- Standards promulgated by the Colorado Water Quality Control Commission,
- The body of regulations governing natural resource (ecological) management,
- Site-specific monitoring and cleanup agreements, and
- DOE Orders and technical guidance

1.1 Integrated Monitoring Plan

The Fiscal Year (FY) FY98/FY99 IMP is a revision of the FY97 IMP and the FY97 *IMP Background Document* (Kaiser-Hill, 1998) which describe the activities being conducted at the Site under the Integrated Monitoring Program to satisfy RFCA and other regulatory requirements and interests. The FY98/FY99 *IMP Background Document*, also developed during this review period, provides detailed discussions of the decision-making process that has resulted in this level of monitoring at the Site. This IMP lists the monitoring programs to which DOE and the other regulatory agencies are committed. The *IMP Background Document* provides additional information on the DQO decision process and the regulatory framework that drives many of the monitoring decisions at the Site.

Both the IMP and the *IMP Background Document* will continue to change with time. Revisions in FY98 have captured both minor and relatively major changes in several of the programs that have either been implemented in FY98 or are planned for FY99 implementation. An example of a relatively major change, implemented during FY98, is the use of project-specific air monitoring guidelines to provide monitoring around environmental restoration (ER) and decontamination and decommissioning (D&D) projects. Such monitoring, while not specifically driven by regulatory requirements, responds to stakeholder concerns about project emission potentials and effectiveness of project controls. Similar guidelines were also developed for project-specific groundwater monitoring. Still pending are guidelines for data presentation to the public, an effort that will rely heavily on public involvement during their development.

This IMP lists the ongoing environmental monitoring activities that DOE, CDPHE, EPA, and other stakeholders have supported during the numerous working group meetings used to formulate the monitoring-based decisions represented here. The document provides an overview of the requirements for these activities and the intended uses of the data that result. The monitoring is performed in four primary areas—surface water, groundwater, air, and ecological systems. Interactions among these media have been recognized and discussed in some detail. The data that are being collected can be used to support investigations into these interactions to the extent that the interactive effects are themselves measurable. Each of the four major monitoring programs is discussed below. In addition, a fifth medium, soil, and its related monitoring is discussed. These soil data relate to all of the other media in some way and continue to be important to the other programs, to future projects and project planning, and ultimately to Site closure. A discussion of soil monitoring at the Site is included in Section 6 of the *IMP Background Document*.

1.2 Data Quality Objectives

Representatives of DOE, Rocky Flats Field Office (RFFO), Kaiser-Hill, and the various federal, State of Colorado, and local stakeholder agencies together developed a set of DQOs to ensure that environmental monitoring data would satisfy the requirements of the regulatory framework described above and would prevent unacceptable risks to public health and the environment. The data will be used to model contaminant movement and identify contaminant concentrations that exceed pre-established limits, support planning, implementation, and assessment of Site remedial and D&D activities, address regulatory reporting requirements and commitments, and monitor various ecological systems at the Site. Therefore, the data need to meet or exceed quality requirements to be useful in modeling, risk assessment, performance assessment, and compliance. The data must be of sufficient quality to withstand scientific and legal scrutiny, and they must be gathered using procedures that are appropriate for their intended use in making decisions for Site activities. Each environmental monitoring program includes a set of data usability requirements and procedures to ensure that high-quality data are produced.

All sampling procedures and analyses of surface water and groundwater adhere to general groundwater DQO guidance, and many also are subject to project-specific quality assurance/quality control (QA/QC) criteria. The *IMP Background Document* details the overall QA/QC requirements, including field duplicate and blank samples, analytical detection limits, and standards for accuracy and completeness. A standardized set of operating procedures (OPs) ensures consistency in sampling and field measurement techniques, and all field sampling crews are trained in those techniques. Refer to the *IMP Background Document* for specific OPs and additional literature concerning QA/QC requirements.

2.0 SURFACE WATER

2.1 Introduction

The surface water monitoring program at the Site addresses the requirements of statutes, regulations, orders, and agreements, and supports many decision-making processes. Surface water monitoring (summarized in Table 1) encompasses five areas:

- Site-wide water quality,
- Quality of waters within the Industrial Area,
- Quality of discharges from the Industrial Area,
- Quality of water leaving the Site, and
- Off-site water quality

Protocols for sampling and analysis of surface water, as well as QA/QC requirements, are defined in several documents. Refer to Section 2.1.5 of the *IMP Background Document* for details.

The Site maintains surface water data in the Rocky Flats Soils and Water Database (SWD) (formerly the Rocky Flats Environmental Database System, or RFEDS), and the data can be retrieved for specific purposes. Many of the data generated are not specifically reported in Site documentation, but rather are provided to requestors or decision makers as needed. However, regular reporting requirements are as follows:

- National Pollutant Discharge Elimination System (NPDES) permit compliance reporting requires monthly and annual preparation and delivery of the Discharge Monitoring Report (DMR) to EPA Region VIII
- Pre-discharge and community assurance monitoring results gathered by the State are reported routinely to the Site and nearby cities
- Exceedances of RFCA standards and action levels are reported to EPA and CDPHE
- The bulk of the surface water data collected are summarized and reported at Quarterly Information Exchange Meetings, which have been held since 1972

Table 1
Surface Water Monitoring Matrix

Type of Monitoring	Locations	Sampling Frequency	Sampling Performed By	Purpose
Site-Wide				
Dam Operations (IDLH)	All detention ponds	Various regular intervals	Site personnel	Assess need for discharges from ponds to ensure dam integrity
Streamflow	7 stream locations	Continuous when flowing	Site personnel	Determine streamflow upgradient of Ponds A3, A4, B5, and C2 Determine outflow from Ponds A4, B5, and C2
Pond Elevations	4 pond locations	Daily (hourly if needed)	Site personnel	Monitor amount of water detained in Ponds A3, A4, B5, and C2
Piezometers	Dams at Ponds A3, A4, B1, B3, B4, B5, and C2	Continuous	Site personnel	Monitor level of saturated zone in detention structures
Dam Integrity Inspections	12 dams	Various	Site personnel, FERC, and DOE	Assess physical integrity of earthen dams
<i>Ad Hoc</i>	Varies	As needed ¹	Site personnel	Address need for special monitoring
New Contaminant Sources	Varies	As needed ¹	Site personnel	Identify source(s) of any new contamination detected by the surface water monitoring program
Plutonium Correlation	POCs, plus 5 additional locations	As needed ¹	Site personnel	Correlate plutonium concentrations to levels of more easily measurable parameters
Industrial Area				
New Source Detection	5	As needed ¹	Site personnel	Detect changes in Aol concentrations or water quality parameters that might indicate new contamination
Incidental Waters	Varies	As needed ¹ (100-200 events/yr on average)	Site personnel	Determine acceptable disposal method
Performance Monitoring (Source Location)	Varies	As needed ¹ , generally from 18 months before project start-up to 3 months after completion	Site personnel	Establish baseline conditions and monitor effects of Site activities on water quality
Industrial Area Discharges to Ponds				
Stream Segment 5	3 Action Levels and Standards Framework (ALF) locations	Varies ¹ (total approx 85 samples)	Site personnel	Monitor compliance with RFCA action levels

Table 1
(Continued)

Type of Monitoring	Locations	Sampling Frequency	Sampling Performed By	Purpose
Internal Waste Streams	Discharges from buildings, WWTP, terminal ponds, and cooling towers, plus any new discharges	Various intervals, depending on location	Site personnel (EPA Region VIII conducts annual NPDES permit inspections)	Confirm NPDES permit compliance
Discharges to WWTP	New waste streams	As needed ¹	Site personnel	Consider for discharge to WWTP
WWTP Collection System	2 locations in collection system	Regular intervals specified in Site procedures	WWTP (Site) personnel	Check for signs of corrosivity and monitor LEL
WWTP Radiological Monitoring	WWTP influent collection lines and effluent	Influent monthly, effluent monthly	Site personnel	Monitor impact of cleanup activities on WWTP and determine removal efficiency
NPDES-Permitted Discharges	WWTP outfall and terminal pond discharges	Specified in NPDES permit	Site personnel	Demonstrate permit compliance and provide data for permit updates
Water Leaving the Site				
Predischarge	Ponds A4, B5, and C2	Approximately 8-10 events/yr (1 per yr at C2)	Site personnel (CDPHE analyzes samples)	Determine quality of water to be discharged from terminal ponds
Terminal Ponds	3 terminal ponds	Frequency specified in NPDES permit or RFCA/POPs Plan	Site personnel	Verify that industrial discharges do not endanger waters of the U S
Segment 4	5 locations	Approximately 3 samples for each of 8-10 discharge events, plus 1-3 samples per month between discharges ¹	Site personnel	RFCA point of compliance (POC) monitoring
Non-POC at Indiana St	Walnut Cr & Woman Cr Drainages	Total of 21 samples annually	CDPHE	Assess effects of flow changes on nutrient loads in water leaving the site

Table 1
(Continued)

Type of Monitoring	Locations	Sampling Frequency	Sampling Performed By	Purpose
Off Site				
Uncharacterized Discharges	5 primary locations, but could vary with circumstances of discharge	As needed ¹	Site personnel	Assess impact of uncharacterized discharges on community water supply facilities
Community Assurance	4 points in Westminster and Broomfield water treatment process streams	Weekly, with samples composited semiannually or annually	Westminster and Broomfield municipal employees	Notify municipalities in the event of water quality exceedances, provide data for dose reconstruction studies

¹ Sampling frequency is determined based on project plans (Refer to IMP Background Document for more information)

WWTP	=	Wastewater Treatment Plant

2.2 Site-Wide Water Quality

This section deals with surface water monitoring objectives that are not confined to a particular area of the site. Site-wide monitoring includes

- Monitoring the dams that form the Site detention ponds (dams lie within a defined area, but monitoring is performed to ensure their effectiveness),
- Locating the source of any contamination detected by the monitoring objectives described in subsequent sections of the IMP,
- Specific monitoring activities in response to requests (i.e., *ad hoc* monitoring),
- Monitoring to establish a correlation between plutonium concentrations and levels of indicator parameters, and
- Monitoring performed for operational reasons and BMPs but not enforceable under RFCA or other federal and state laws and regulations

The Site-wide monitoring is described below

2.2.1 Monitoring Dam Operations

The Site detention ponds (Figure 1) are formed by earthen dams, which are designed for stormwater detention. Water is routinely discharged from the ponds as levels rise, once water quality is determined to meet downstream standards. Although water rarely rises to the elevation of emergency spillways, if that were to happen, there is a risk that the dams could fail or sustain damage.

The Site uses data from the monitoring activities listed below, along with water quality data from the ponds, within a specific decision-making process (see *IMP Background Document*, Section 2.2.1 and ancillary documents cited therein) to determine if and when water should be released from the ponds. The Site performs the following monitoring activities:

- Measure streamflow upgradient of Ponds A3, A4, B5, and C2, measure outflow from Ponds A4, B5, and C2,
- Monitor pond elevations continuously in terminal Ponds A3, A4, B5, and C2 [daily monitoring is adequate for normal operations,

hourly monitoring is invoked as established by procedure (e.g., in response to storms) to ensure dam safety],

- Monitor piezometers installed in the dams to track the level of the saturated zone in the earthen detention structures,
- Evaluate dam integrity through visual inspections at appropriate frequencies as determined by procedure,
- Perform routine integrity inspections on dams on all 12 ponds at appropriate frequencies as determined by *Pond Operations Plan* (POps Plan) (Kaiser-Hill et al., 1996), and perform a detailed internal inspection biannually [Federal Energy Regulatory Commission (FERC) and DOE inspect dams externally on an annual basis],
- Monitor spatial position of the crest monument to detect movement, if any as required by the Colorado State Engineer's dam safety regulations,
- Monitor the inclinometers and evaluate dam crest movements quarterly to identify any movement of dam structure, and
- Exercise the valves in the outlet works of the terminal dams to ensure operability, as directed by the Office of the State Engineer

Figure 1. Schematic Surface Water Map

Data are entered into a spreadsheet model to assess the need for discharge, based on the *Pond Operations Plan*. Meteorological data are also used in the model, along with inflow and discharge rates as applicable.

2.2.2 Locating New Contaminant Sources

If new contamination is indicated by surface water monitoring, the Site may use portable sampling equipment to help determine its source. This monitoring may cross the boundaries of other surface water monitoring objectives. For instance, if contaminants are detected outside the Industrial Area, portable sampling equipment may be deployed inside the Industrial Area to locate the source (see *IMP Background Document*, Section 2.2.2).

2.2.3 Ad Hoc Monitoring

Ad hoc monitoring is designed to address specific identified data needs. The data needs arise in response to circumstances that are not addressed by the routine monitoring program. *Ad hoc* monitoring falls into one of two categories:

- *Required*—Statutory, regulatory, permit, or order requirements that monitoring must be done to obtain analytical data, and
- *Discretionary*—Where analytical data could help with further decision making, or a need for additional data is otherwise strongly indicated.

Ad hoc monitoring may be conducted in response to events such as unusual precipitation volumes, community concerns, changes in permit or regulatory requirements, construction projects, operations, or spills.

2.2.4 Monitoring for Correlation of Plutonium with Indicator Parameters

The Site continues to study whether a correlation can be established between plutonium concentrations and levels of indicator parameters that can be measured frequently, or even continuously, at much less expense than radiochemically analyzing samples for plutonium. For instance, total suspended solid (TSS) concentrations may provide an indication of plutonium concentrations, because plutonium and other radionuclides tend to adsorb to particulate matter in surface water. Although measuring TSS requires a laboratory analysis, the lag time between sample collection and data delivery is considerably shorter than for a radiochemical analysis. Turbidity, which can be measured continuously, may also correlate with plutonium concentrations. If so, continuous turbidity measurements would provide an early indication of potential rising plutonium concentrations, improving the protection of public health and the environment. The technical hurdle in this effort remains the issue of sensitivity: identifying correlations at very low concentrations challenges the available analytical methods.

Plutonium concentrations are already being monitored at the terminal pond outfalls and at the Indiana Street RFCA points of compliance (POCs). The Site also monitors TSS concentrations when possible at these five stations. In addition, the Site monitors, when possible, TSS and turbidity at stations SW022, GS10, SW093, SW091, and SW027, which are located sufficiently upstream in Segment 5 that they would provide at least 2 hours warning before exceedances could occur in Segment 4. The Site also monitors precipitation at several locations.

The Site will evaluate the data from this monitoring objective to study the correlation between plutonium concentrations and levels of indicator parameters. Based on this analysis, this monitoring objective may be modified in the future to further define any correlations observed.

2.3 Water Quality Within the Industrial Area

The Site monitors waters within the Industrial Area to detect new sources of contamination, assess the performance of facilities or project elements (e.g., during closure of a facility) in preventing releases of specific constituents, and monitor the quality of incidental rainwater or snowmelt that may accumulate in utility pits and bermed areas. Indications of a contaminant release would trigger reporting and decision-making for response and/or remediation. The Site conducts the following activities under this portion of the surface water monitoring program:

- Project-specific performance monitoring,
- Management of incidental waters,
- Sanitary system monitoring including
 - Characterize internal wastewater streams for NPDES permit compliance,
 - Monitoring discharges to the Wastewater Treatment Plant (WWTP), and
 - Monitor total flow, potentially dangerous or damaging waste streams, and radiological activity of influent to the WWTP,

- WWTP influent monitoring,
- WWTP collection system monitoring

2.3.1 Incidental Waters

Approximately 100–200 occurrences of incidental water at the Site require monitoring each year. Waters that accumulate in utility pits, berms, footing drains, sumps, and excavation sites, or that are released within buildings or onto the ground, are evaluated using field screening observations and measurements, coupled with the process knowledge of Site personnel. Additional analysis is required if the circumstances or field observations provide cause to suspect the presence of oil or hazardous/radioactive constituents.

The program for monitoring incidental waters provides for routine, data-driven decision making on whether to allow discharge of these waters into the environment without treatment. In evaluating incidental water, field personnel estimate the volume of water present, note its appearance (especially its color or presence of a visible sheen), and field test its pH, nitrate level, and conductivity. In conjunction with knowledge of the processes occurring in the immediate vicinity, these data guide the process of deciding how to dispose of the incidental waters. Waters that cannot be discharged to the environment may be considered for discharge to the WWTP (under internal wastewater stream rules) or may be managed under other applicable regulations.

2.3.2 Sanitary System Monitoring

Sanitary collection system monitoring may provide the Site D&D project managers and WWTP operators information about collection system condition within the Industrial Area as specific areas contributing to the WWTP flow. Current and prospective monitoring systems provide information about the relative contribution of the two main branches of the sanitary collection system and qualitative information about the content of flows through the headworks of the WWTP. Sanitary system monitoring is conducted to

- Determine percent removals across the treatment plant and therefore be able to predict compliance or noncompliance with NPDES permit effluent limitations
- Monitor explosive levels at the headworks for worker safety
- Monitor for corrosive substances that may impact the treatment units
- Determine if influent concentrations and loads are trending up or down
- Monitor within the collection system to establish pollutant loads attributable to specific industrial internal waste streams (such as the laundry water at the Site)

Five distinct monitoring objectives have been identified for sanitary system monitoring. Separate decision rules have been developed for each of these objectives.

2.3.2.1 Characterization of Internal Wastewater Streams

The first monitoring objective is to characterize routine internal waste streams to meet NPDES permit requirements (see *IMP Background Document* Section 2.3.2.1 - Internal Waste Stream Characterization to Meet Permit Requirements). Data on internal wastewater streams are used to make decisions regarding the disposition of contaminated waste water produced on the Site. Monitoring is needed because some wastewater requires treatment and some can be discharged to the WWTP. The data are used to determine whether discharges to the WWTP are compatible with the activated sludge, exceed the facility's ability to handle it, and comply with the Site's NPDES permit.

The existing NPDES permit also covers all discharges to surface water (including the WWTP outflow). Site personnel use monitoring data to maintain the permit and to renew the permit every five years. Both permit maintenance and renewal may require modifying specific conditions, particularly as Site closure activities accelerate. (Note: A new NPDES permit for the Site is anticipated to be effective January 1, 1999.) The NPDES permit specifies all managed and incidental discharges to be monitored, including all sanitary discharges and process wastewater streams from Site buildings, along with discharges from Building 374, the WWTP, and the terminal ponds. Any new wastewater streams must be characterized and monitored as well. In addition, the cooling towers are being monitored pending a decision on whether their discharge should be included in the permit. Site personnel must fully disclose all wastewater streams to EPA Region VIII, which conducts annual NPDES permit inspections of the Site to enforce this disclosure requirement.

2.3.2.2 Monitoring Discharges to the WWTP

This monitoring objective is distinct from the nonroutine objective, for which a distinct decision rule has been developed (see *IMP Background Document* Section 2.3.2.2 - Monitoring Discharges to the WWTP). Any new wastewater streams generated on the Site must be evaluated to determine how best to dispose of them. Most can be discharged to the WWTP under the terms of the NPDES permit but some cannot. The latter must be disposed of in accordance with applicable requirements. Site personnel screen all wastewater streams for visible sheen, color, clarity, volume, field conductivity, and pH. However, the most important factor in determining the means of disposal is knowledge of the specific process that produces the wastewater. This information is considered in making decisions regarding disposal of wastewater streams.

2.3.2.3 Monitoring the WWTP Collection System

Finally, monitoring of the WWTP influent flows include collection system flow monitoring, protective monitoring, and radiological influent monitoring. WWTP

personnel regularly check the WWTP collection system at two locations for pH, conductivity, and lower explosive limit (LEL) They also take manual pH readings at the headworks Conductivity and pH are indicators of corrosivity, which could damage the treatment equipment, and LEL readings are taken to ensure worker safety Additional monitoring activities added for FY99 include collection system flow monitoring and influent radiological activity This monitoring is added to ensure that the plant effectively processes wastewaters that change as Site closure activity increases The WWTP monitoring objectives and decision rules are described in the *IMP Background Document* Section 2 3 2 3 - WWTP Collection System Protective Monitoring, Section 2 3 2 4 - WWTP Collection System Flow Monitoring, and Section 2 3 2 5 - WWTP Radiological Monitoring, respectively

2.3.2.4 WWTP Collection System Flow Monitoring

Flow information for the Site's sanitary collection system is currently limited to influent records for the WWTP The initial scope of collection system monitoring is intended to provide Site collection system flow information by installing continuous recording flow monitoring equipment at B990 on the two main collection system lines The flow record will be used to establish annual baseline conditions for the flows from the Protected Area (PA) and non-PA areas Changes from the established baseline flow may be attributable to normal collection system conditions such as infiltration and inflow, or abnormal conditions, such as increased flows from areas undergoing D&D

2.3.2.5 WWTP Radiological Monitoring

This section also includes the monitoring of radiological parameters at the influent to the WWTP for the purpose of tracking pollutant loads coming through the WWTP collection system The assumption is that these radiologic loads to the WWTP should be decreasing, since the Site has systematically tried to eliminate any possible connections between waste streams containing radionuclides and the collection system

2.3.3 Performance Monitoring

Performance monitoring may be specified for individual projects (e g , D&D, specific remedial activities, transition actions, or BMPs for transport and fate of plutonium in surface water runoff) within the Industrial Area ¹ In general, such project-specific

¹ Although performance monitoring may be conducted at any location on the Site, the majority occurs within the Industrial Area

monitoring targets 18 months of data prior to project startup to establish baseline conditions, and continues for 3 months after project completion. The Site recently conducted performance monitoring at Buildings 886, 779, and 123.

2.3.4 Monitoring NPDES Discharges to Ponds

The NPDES permit program controls the release of pollutants into the waters of the United States and requires routine monitoring of point source discharges and reporting of results. In the current Site permit, six monitoring points are specified for control of discharges. These locations include the effluent of the WWTP, two interior ponds, and three terminal ponds capable of discharging water off site. The NPDES permit terms were modified by the Federal Facility Compliance Agreement (FFCA) signed on March 25, 1991 (DOE, 1991). Modifications included the elimination of inactive discharge points and inclusion of new monitoring parameters at other discharge locations.

Permit negotiations are currently underway to revise the Site permit. The revised draft permit for the Site is expected to address only two permitted discharge points, the WWTP effluent and Building 374 product water effluent. The revised permit specifies WWTP effluent to be discharged directly downstream of the terminal ponds, in effect bypassing the stormwater detention pond system. The other previously permitted discharge locations will be regulated under CERCLA via the RFCA.

2.4 Industrial Area Discharges To Ponds

Industrial Area discharges to the ponds include surface water runoff, discharges from the wastewater treatment plant (WWTP), and waters in Segment 5 (including the stream channels and interior ponds). Under this portion of the surface water monitoring program, the Site monitors

- Segment 5 water quality, and
- NPDES-regulated discharges to the ponds

2.4.1 New Source Detection

The Site collects surface water samples at stations SW022, SW091, SW093, SW027, and GS10, which are located in the upper reaches of the three main drainages through which runoff leaves the Industrial Area. Analytes of interest (AoIs) include plutonium, uranium, and americium isotopes, water quality parameters, including turbidity, pH, nitrate, and conductivity (measured every 15 minutes), and precipitation data (measured continuously at SW022) and flow rate (measured continuously). Additional AoIs also may be identified.

The "indicator parameters," those that can be and are monitored continuously, provide a qualitative early warning of potential contaminant releases without the long turnaround time or cost of more frequent sample analyses for the specific contaminants. For example,

plutonium and americium concentrations are generally correlated with TSS which correlates with turbidity, and plutonium may be correlated with nitrate concentrations. Additionally, levels of chromium, beryllium, silver, and cadmium may correlate with conductivity readings. If a continuously monitored parameter provides cause for concern about a particular contaminant, samples may be collected and analyzed for that contaminant.

2.4.2 Stream Segment 5

The Site monitors Segment 5 water quality (as represented by stations SW093, SW027, and GS10) for compliance with RFCA action levels. Exceedances require development of a response action plan.

The RFCA Action Levels and Standards Framework (ALF) provides criteria for identified contaminants. A subset of these contaminants are monitored under this portion of the program (see Table A-26 in the *IMP Background Document*). The Site collects samples (one to four per month depending on flows) from each station for an estimated total of 85 samples during the year (see Table 2-14 in the *IMP Background Document*). The number of samples collected from each station is determined using historical flow data, collecting approximately 10 liters (L) of water for each 500,000 gallons of stream flow to a maximum of four per month, and targeting each 15-L sample composite to contain approximately 50 flow-paced grab samples.

Collecting only one sample per month and analyzing only for the AoIs listed above would be sufficient to comply with RFCA requirements. However, the higher number of samples reduces the chance of recording a false exceedance or of missing a short-duration contaminant surge. Sampling frequency may be adjusted to accommodate changing data needs.

2.5 Water Leaving the Site

Water leaves the Site in Stream Segment 4 at Indiana Street, and the Site performs four monitoring objectives to assess its quality:

- PredischARGE monitoring,
- NPDES monitoring of terminal ponds as required by the current Site permit,
- RFCA POC monitoring of Segment 4, and
- Additional, non-point of compliance (non-POC) monitoring

2.5.1 Predischarge Monitoring

Before water is discharged from the Terminal Ponds, it must be evaluated for a range of constituents to ensure that unexpected contaminants have not been introduced. Therefore, the Site collects predischarge samples 8 to 10 times per year from the Walnut Creek Drainage at Ponds A4 (North Walnut Creek) and B5 (South Walnut Creek), once per year from the Woman Creek Drainage at Pond C2, and as needed from any other ponds temporarily functioning as a terminal pond. CDPHE analyzes the samples for an extensive list of constituents, including inorganic compounds, metals, volatile and semivolatile organic compounds, radiologic parameters, herbicides, and pesticides (see Table 2-16 in the *IMP Background Document* for analyte list and sampling targets). The sampling and analyses are conducted far enough in advance of a planned discharge to allow action to be taken if exceedances are noted, but near enough to the time of discharge to be representative of the discharge composition.

2.5.2 Segment 4 Compliance Monitoring

The Site performs RFCA POC monitoring at five stations in Segment 4 (GS11, GS08, GS31, GS03, and GS01). POC monitoring is concerned primarily with concentrations of plutonium, americium, and tritium, although additional analytes are monitored in a subset of samples. Approximately three samples are collected during each pond discharge event (approximately 8 to 10 discharge events per year, see Table 2-19 in the *IMP Background Document* for POC monitoring targets), and flow-proportional sampling is conducted between discharges when flow rates are sufficient to obtain required water sample volumes.

2.5.3 Non-POC Monitoring at Indiana Street

Various off site reservoir construction and water diversion projects will cause changes in the surface water flow regime. The CDPHE conducts additional monitoring to assess the effects of these flow changes on nutrient loads in water leaving the Site. CDPHE collects samples periodically from Walnut Creek to assess the composition of the water when it consists of

- 100% Site effluent (five samples),
- Mixed effluent and natural stream flow (five samples), and
- 100% natural stream flow (five samples)

In addition to these 15 samples, CDPHE collect 5 samples from Woman Creek during times when Pond C2 is not discharging and 1 sample during Pond C2 discharge. All 21 samples are analyzed for total ammonia, nitrite, nitrate, phosphate, orthophosphate, uranium isotopes, beryllium, cadmium, silver, and chromium. (In the future, the latter four metals may be deleted from the analyte suite, depending on initial water quality results.)

2.6 Off-site Monitoring to Support Community Water Supply Management

Site and CDPHE personnel provide monitoring data to nearby communities for their use. Procedures are in place to monitor uncharacterized discharges from the Site and to provide data that address public concerns regarding water quality.

2.6.1 Monitoring Uncharacterized Discharges

This monitoring would normally be required only if monitoring specified under the previous decision rules is not performed in accordance with the sampling and analysis protocols, e.g. POC and POE monitoring at Indiana Street, or if flow leaving the Site exceeds the capacity of the downstream ditch or reservoirs.

If surface water of unknown quality (unmonitored) leaves the Site, it is necessary to demonstrate that the water quality is acceptable to the downstream users. Examples include:

- Unmonitored storm flow exceeds the capacity of Broomfield's diversion ditch and enters Great Western Reservoir, and
- Water quality in downstream waters that may have been impacted by unmonitored effluent from the Site.

2.6.2 Community Assurance Monitoring

Several factors have made it necessary for the communities to reassure residents that their environment is safe, including RFETS' past mission as a nuclear weapons production facility, the nature of the contaminants, the history of releases and accidents, and the geographic and hydrologic relationship of the Site to the neighboring municipalities. Adequate and timely information regarding the impact of the Site is necessary. The level of concern fluctuates with activities at the Site but may be expected to continue as long as environmental contamination and special nuclear materials are present at the Site.

Since the completion of the Standley Lake Protection Project and the Great Western Reservoir Replacement Project, which were designed to protect the potable water supplies, routine monitoring of the municipal treatment and distribution systems is no longer warranted. However, Great Western Reservoir is still used as an irrigation supply, and the fact that the reservoir is considered to be unsuitable for potable use raises questions on the part of irrigation customers. Therefore, during FY98/FY99, community assurance monitoring continues at Great Western Reservoir as specified in Section 2.6.2 of the *IMP Background Document*.

3.0 GROUNDWATER

3.1 Purpose

Most of the groundwater at the Site is hydraulically connected to surface water. The groundwater monitoring program (Table 2) is designed to accomplish the following:

- Detect and identify contaminants in groundwater and monitor their concentrations,
- Identify contaminant sources and monitor remediation efforts,
- Delineate contaminant pathways,
- Assess the effects of Site remediation and closure activities,
- Protect groundwater from new sources of contamination, and
- Evaluate any effects of contaminated groundwater on surface water

3.2 Monitoring Focus

Several contaminant plumes have been identified in Site groundwater (see Appendix D and Plate 3 in the *IMP Background Document*). The main contaminants of concern (COCs) are volatile organic compounds (VOCs), which originated from the Site's historical chemical use and storage during its years of producing nuclear weapons components. Possible sources of contaminants that could affect groundwater include storage tanks, the process wastewater system, drains, sumps, historical storage areas, and spills. The monitoring scope is designed to be conducted before, during, and after Site operations that may affect groundwater quality.

Site personnel determine the concentrations of groundwater Aols and compare them to established background levels, as well as to Site action levels or standards. They evaluate exceedances of these criteria to determine whether the data demonstrate an ongoing trend, and they factor the presence or absence of discernible trends into the Site decision-making process (see Section 3.4.2 of the *IMP Background Document*) to assess the need for new remediation efforts or changes in ongoing activities.

Water-level measurements are incorporated into water elevation maps and hydrographs to define groundwater gradients and flow rates. Both the program for measuring water levels and the sampling and analysis program provide temporally related data for use in direct comparisons from year to year.

Table 2
Groundwater Monitoring Matrix

Type of Monitoring	Locations	Sampling Frequency	Purpose
Sample for determination of analyte concentrations	86 wells	Semi-annual	Monitor analyte concentrations in groundwater
Sample for determination of analyte concentrations	12 wells	Quarterly	Monitor analyte concentrations in groundwater
Water-level measurement	72 wells	Monthly	Characterize groundwater flow regime
Water-level measurement	68 wells	Quarterly	Characterize groundwater flow regime
Water-level measurement	100 wells	Semi-annual	Characterize groundwater flow regime
Water-level measurement	25 wells	Real-time	Characterize groundwater flow regime

3.3 Monitoring Program

The groundwater monitoring program comprises the following components (see Appendix E in the *IMP Background Document*)

- Semi-annual sampling in a network of 86 wells,
- Quarterly sampling of 12 wells and seeps,
- Monthly measurement of water-table elevations in 72 wells,
- Quarterly measurement of water-table elevations in 68 wells,
- Real-time measurement of water-table elevations in 25 wells,
- Semi-annual water level measurement in 100 wells,
- Data interpretation and reporting,

- Database management, and
- Well abandonment and replacement program (WARP)

3.3.1 Well Locations

Wells have been installed along known or suspected pathways between contaminated areas and outlets to surface water. The majority of the wells are located around the perimeter of the Industrial Area, the former Operable Unit 2 (OU2) and the existing landfill. Additional wells are located within the Site drainages, because stream flow is ephemeral. Boundary wells are maintained at the downgradient (eastern) Site boundary to confirm that contaminants are not migrating off Site. On-Site wells fall into eight categories:

- Plume definition,
- Boundary,
- Plume extent,
- Performance,
- Drainage,
- Closure activities,
- RCRA (covers monitoring of permitted wastewater storage units), and
- Plume degradation

3.3.2 Groundwater Sampling and Analysis

Field crews measure groundwater temperature, pH, specific conductance, turbidity, and alkalinity, and submit a sample to a laboratory for measurement of total dissolved solids (TDS). They collect filtered samples for determination of metals concentrations and uranium isotopes. They also collect unfiltered samples for organic compound analyses, water quality determination, and measurement of all other radionuclides. Analytes of concern vary among wells, depending on the particular constituents in the plume being monitored. The scopes of work for the analytical laboratories contain complete target analyte lists (TALs).

The groundwater flow regime at the Site is such that sample volumes from some wells may be limited. If an available sample volume precludes determination of the entire analyte suite for a particular well, the analyses are performed in the following order of priority:

- VOCs [Contract Laboratory Program (CLP) Method 524 2],
- Semivolatile organic compounds,
- Pesticides and polychlorinated biphenyls (PCBs),
- Nitrate/nitrite, as nitrogen,
- Screening analysis for radionuclides,
- Metals (TAL, plus cesium, lithium, strontium, tin, molybdenum, and silica),
- Any specific metals for a particular well (see TALs),
- Uranium-233/234, -235, -238,
- Strontium-89/90,
- Plutonium-239/240 and americium-241,
- Major anions (chloride, fluoride, sulfate, carbonate/bicarbonate), and
- Tritium

3.4 Data Disposition

3.4.1 Databases

Site personnel enter all field data and analytical data into the SWD. They maintain data integrity through the use of standard data entry OPs and by running error-checking routines when loading data.

Data can be extracted for various uses, including using the geographic information system (GIS) to map constituent distribution, and using various analytical models to assess groundwater movement and constituent migration.

3.4.2 Reporting

Groundwater monitoring activities are reported through the following vehicles:

- RFCA Annual Groundwater Report: Quarterly reporting at the Quarterly Information Exchange Meeting presents data gathered during the reporting period, provides notification of any exceedances of RFCA groundwater action levels, and lists required actions for exceedances. The Annual

Groundwater Report replaced various previously required reports and serves as the primary compliance report

- RFCA Quarterly Reporting These data replace all previous quarterly reporting, integrating the elements of each regulatory driver into a single reporting vehicle Quarterly reporting at the Quarterly Information Exchange Meeting summarizes data gathered during the reporting period and also provides notification of any exceedances of RFCA groundwater quality standards
- IMP The IMP is the vehicle for changing required groundwater monitoring program elements It is reviewed and updated annually

3.5 Well Abandonment and Replacement Program (WARP)

Section 3 6 7 of the *IMP Background Document* describes the WARP, which specifies the approval process for well installation and ensures proper recording and registration of all well installation activities Site personnel maintain a database of all well locations, construction, permitting, and other relevant information They also maintain a core repository for use in hydrological and geological characterization

Wells are considered for abandonment if they are damaged or poorly constructed (or construction details are unknown), present a potential for cross contamination of other wells or the aquifer, or no longer needed Activities conducted under the WARP are reported in the RFCA Annual Report

4.0 AIR QUALITY

4.1 Purpose and Programs

The air monitoring activities on the Site (Table 3) assist in protecting the public and the environment by detecting and tracking the impacts of Site operations on air quality at and near the Site, characterizing any airborne materials that may be introduced, and monitoring the meteorological conditions that influence the transport and dispersion of airborne materials. Data are used to plan, implement, and assess the effects of on-Site activities, including operations, construction, and closure activities, maintain emergency preparedness, and demonstrate compliance with relevant regulations.

The Air Quality Management (AQM) group within Kaiser-Hill's Environmental Compliance and Operations organization develops the scope for Site air monitoring and reporting activities required to maintain compliance with applicable air quality regulations and DOE Orders. In addition, CDPHE conducts oversight monitoring.

4.1.1 Ambient Air Monitoring

Ambient monitoring of radionuclides on the Site and at the perimeter is performed by AQM and by CDPHE, which also monitors nonradioactive pollutants on and around the Site. Ambient monitoring in the communities immediately adjacent to the Site is coordinated by DOE. The purpose of these monitoring stations is to characterize any Site-related airborne emissions. The community stations, which monitor airborne plutonium concentrations, are operated independently by members of the communities of Arvada, Westminster, Broomfield, and Northglenn (the Community Radiation Program, or ComRad).

4.1.2 Effluent Monitoring

Air emissions (effluent) from Site facilities that contain significant quantities of radioactive materials are monitored continuously in accordance with state and federal regulatory requirements and are used to verify the effectiveness of radiation control mechanisms. Facilities with lesser potential to emit radionuclides are monitored periodically to verify low emissions. Emissions data are also used as part of the evaluation process to keep radioactive emissions as low as reasonably achievable.

4.1.3 Meteorological Monitoring

Instruments continuously monitor meteorological conditions at the Site to generate data for use in air dispersion models that predict the transport of airborne emissions. Site

Table 3
Air Monitoring Matrix

Type of Monitoring	Locations	Sampling Performed By	Sampling Frequency	Purpose
Ambient air	35 samplers	Site personnel (AQM)	Continuous	Detect and characterize Site-related airborne emissions
	Additional samplers on Site and at perimeter	CDPHE	Continuous	Detect and characterize Site-related airborne emissions
Effluent from Industrial Area facilities	52 exhaust outlets	Site personnel (AQM)	Monthly from significant sources, annually from insignificant sources (filters collected monthly and composited)	Comply with state and federal regulatory requirements for monitoring and verify effectiveness of radiation control mechanisms
Meteorology	1 tower with instruments at ground level and at 10, 25, and 60 m, 1 backup tower with instruments at 10 m	Site personnel (AQM)	Continuous	Monitor meteorological conditions for use in air quality modeling
	5 towers at Site perimeter	CDPHE	Continuous	Provide data as needed for emergency response modeling
Project specific	Selected subset of existing ambient air monitoring locations	Site personnel (AQM)	Continuous, filters exchanged weekly	Assess impacts of remediation or D&D projects, provide data to better characterize airborne emissions

Notes

m = Meter

AQM = Air Quality Management

personnel use model predictions to evaluate Site operations and closure projects, and for emergency preparedness

4.2 Site Air Monitoring Scope

Ambient air monitoring and effluent monitoring are performed at the Site to satisfy requirements of Title 40 of the *Code of Federal Regulations*, Part 61, Subpart H, "National Emission Standards for Emissions of Radionuclides Other Than Radon from Department of Energy (DOE) Facilities" (Rad NESHAP) and DOE Orders. CDPHE and the ComRad program perform additional, independent air monitoring

4.2.1 Ambient Air

The Radioactive Ambient Air Monitoring Program (RAAMP) collects ambient radioparticulate air data. The RAAMP network comprises 35 samplers. Twelve of these existing samplers have been included in a proposal to satisfy regulatory compliance demonstration requirements under the CAA using environmental measurements, the others are used for backup should there be accidental releases from the Site or for determining local impacts from remediation projects. The samplers run continuously, collecting airborne particulates on pairs of filters that represent different size fractions. Personnel collect the filters regularly, submitting them for analysis for specific isotopes of plutonium, uranium, and americium. The *IMP Background Document* details specific sampling intervals and analytical detection limits.

The CDPHE also operates air samplers on Site and at the perimeter. The two monitoring networks serve as independent measures of public exposure to radioactive releases, and they also monitor additional analytes, including beryllium, nitrogen dioxide, and non-radiologic pollutants regulated under the National Ambient Air Quality Standards.

4.2.2 Effluent

Exhaust air emissions from all Site facilities that contain radioactive materials (52 locations in the Industrial Area) are monitored by analyzing filters taken from continuous effluent sampling systems. Filters are analyzed monthly from sources considered to be "significant" (i.e., having the potential to contribute more than 0.1 millirem per year effective dose equivalent, uncontrolled, to any member of the public). Filters are collected monthly from "insignificant" sources, and these filters are composited and analyzed annually. In addition to analyzing filters for plutonium, uranium, and americium isotopes, samples are collected three times weekly at five locations for tritium analysis.

4.2.3 Meteorological Conditions

A 61-meter (m) tower is located in the northwest part of the Buffer Zone, with monitoring instruments at ground level and at 10, 25, and 60 m above the ground. A separate 10-m tower nearby provides backup data. Instruments measure wind speed and direction, temperature, and relative humidity (dew point), solar radiation, precipitation, and information used to calculate atmospheric stability class. CDPHE operates five meteorological towers located about the Buffer Zone perimeter, and they provide data from these towers as needed to support Site emergency response modeling.

4.3 Project-Specific Monitoring

Whenever a D&D or environmental restoration project is planned that has a significant potential to release radionuclides, the existing on-Site and off-Site ambient sampler network will be employed to provide project-specific monitoring. Samplers in the immediate vicinity of the project will have filters exchanged weekly instead of monthly. Filters from these "project-specific" monitors will be screened for radioactive contamination and the results compared to predefined notification levels specific to each project and each sampler. If necessary, results of the screening may be used by project personnel to adjust schedule or project controls to ensure Site-wide compliance with state and federal dose standards.

5.0 ECOLOGY

The Buffer Zone around the Industrial Area at the Site is one of only a few areas along Colorado's Front Range that has remained largely undisturbed by encroaching development. The Buffer Zone contains several unique assemblages of animals and vegetation, and the ecological monitoring activities described in this section have been designed by DOE and its contractors to protect these valuable natural resources. Five major vegetation communities have been identified at the Site:

- Xeric tallgrass prairie,
- Tall upland shrubland,
- Great Plains riparian woodland complex,
- High-quality wetlands, and
- Mesic mixed grassland

In addition to the terrestrial vegetation communities, the aquatic communities of the riparian channels and ponds at the Site are monitored for ecological health.

Ecological monitoring is designed to protect wildlife in the Buffer Zone, including any special-concern species (i.e., threatened, endangered, candidate, proposed, state-listed, or other sensitive species). The Preble's meadow jumping mouse is of particular concern because it was listed as a threatened species on May 13, 1998.

5.1 Monitoring Objectives

The Ecological Monitoring Program (summarized in Table 4) is designed to provide data that can be used in management and conservation decision making during Site cleanup activities that will occur over the next decade. Data also demonstrate compliance with applicable natural resource protective regulations.

Site ecologists monitor key variables in the five vegetation communities and other habitats, and changes in any of these variables would trigger ecological protection and compliance decision making. Comparisons of monitoring data from year to year enable ecologists to detect changes, identify potential causes, and plan corrective actions for changes that result from Site activities, rather than from natural fluctuations.

Table 4
Ecological Monitoring Matrix

Basis for Monitoring	Number of Locations	Sampling Frequency	Purpose of Monitoring
Manage and conserve migratory bird species numbers and richness comply with Migratory Bird Treaty Act	20 Transects	15 times per year	Track changes in numbers and richness of migratory birds at the Site
Manage and conserve significant wildlife species and bird species numbers and richness, comply with Endangered Species Act, other federal acts, and Colorado wildlife protection statutes	16 Transects	12 times per year	Track changes in numbers richness, and habitat dependence of significant wildlife species (including birds) at the Site
Manage and conserve significant species numbers and richness, comply with Endangered Species Act, other federal acts, and Colorado wildlife protection statutes	1 Sitewide Survey (Follows all passable Buffer Zone roads)	12 times per year	Track changes in numbers, richness, and area use of significant wildlife species at the Site
Monitor and conserve viable Preble's mouse populations in appropriate habitat and monitor and conserve current coverage of characteristic Preble's mouse habitat Comply with Endangered Species Act and Colorado wildlife protection statutes	Approximately 4 locations per year based on previous year's results	2 times per year (800 trap nights per location per year)	Monitor presence relative populations and habitat dependence of Preble's mouse at the Site
Monitor and conserve unique and rare vegetation communities and develop management strategies for their protection and enhancement	44 Management Units	2 times per year	Track changes in numbers and richness of plant species health of plant communities and changes in areal extent of high-value vegetation communities
Monitor the noxious weeds at the Site, comply with weed control regulations	Variable by year	2 times per year	Evaluate effectiveness of and aid in outyear planning for weed control actions at the Site
Monitor the effectiveness of controlled burning as a management tool for conservation and enhancement of high-value vegetation communities	Variable by year	2 times per year	Evaluate effectiveness of and aid in outyear planning for, controlled burning actions at the Site
Monitor for the presence, or potential presence, of special-concern threatened or endangered plant and wildlife species and wetlands comply with federal state, and local protection and conservation regulations	Variable by year	As required	Ensure compliance of projects with applicable ecological regulations and protect rare threatened and endangered species from harm

5.2 Scope of Monitoring

Site ecologists conduct several types of monitoring in all five vegetation communities, as well as some activities specific to one or more communities. Common to all five vegetation communities are the following activities:

- Define the extant area of the community
- Provide baseline estimates of the presence of birds and mammals, and estimate the baseline species richness of plant, bird, and mammal populations (Plant species richness baseline will be determined from 1993–96 data, and bird and mammal baseline was established in the *1996 Annual Wildlife Survey Report* (Kaiser-Hill, 1997b))
- Identify rare or imperiled plant or animal species
- Make annual estimates of plant, bird, and mammal species richness (Plant data are collected in the spring and summer to ensure that spring ephemerals and late-maturing plants are recorded, and bird and mammal species richness is measured monthly)
- Conduct weed mapping and photo surveys (Photo surveys are conducted in both summer and winter in woody communities and annually in grasslands)
- Make annual assessments of endpoints for the vegetation community and wildlife populations
- Monitor the presence of noxious weeds and the effects of weed control efforts
- Anticipate impacts from proposed Site projects, and estimate the potential area affected

Ecologists also monitor the presence of noxious weeds and changes in plant community characteristics in areas not included within the five vegetation communities defined above. The aquatic monitoring component of the ecological monitoring program includes monitoring for the continued presence and health of fish populations in streams and ponds at the Site. Due to the limited aquatic habitat available, aquatic sampling is not extensive.

5.2.1 Preble's Meadow Jumping Mouse

Populations of Preble's meadow jumping mouse have been identified within areas of tall upland shrubland and Great Plains riparian woodland. Monitoring activities in these areas include

- Annual estimates of plant species richness, density, height, and canopy cover are made
- Characterizing Preble's mouse populations (using all monitoring through 1996 as a baseline) and monitoring the source populations over time. Monitoring concentrates on determining the presence or absence of the species; quantitative population measurements are not appropriate because of its rarity. Monitoring data provide a basis for tracking ratios of males to females and adults to juveniles, enabling population viability to be confirmed. Ecologists monitor the known population areas on a rotating basis through a 2- to 3-year period, depending on results from the previous field season. They trap during May through September because the mouse hibernates over the winter months.

5.2.2 Wetlands

In addition to the activities listed above, the U S Army Corps of Engineers determines the extent of wetlands at the Site every five years. They will conduct the next wetlands evaluation in the year 2000. A comprehensive plan (Kaiser-Hill, 1997c) to manage and protect Site wetlands was issued in 1997, detailing the methods and procedures that will be used to identify wetlands and minimize impacts to them from Site closure and remediation projects.

5.2.3 Project-Specific Monitoring

Proposed Site projects will be evaluated in terms of potential effects on threatened and endangered (T&E) species, species of special concern (SSC), and migratory birds and wetlands. Much of the data for such evaluations will come from the monitoring activities listed above, but additional data needs may be identified to assess the impact of such projects in specific areas. Project-specific data needs may include

- Seasonal presence or absence of affected species, and the seasonal timing of the proposed project,
- Presence of habitat considered suitable for T&E and SSC species, and

- Biological characteristics of species of concern (feeding and nesting habits, home range, habitat preference), and potential effects of the proposed project

Proposed projects will also be evaluated in terms of their impacts to migratory birds and Site wetlands (Wetlands include both those mapped by the U S Army Corps of Engineers and those not included on the map)

5.3 Data Disposition

Ecological data have historically been stored in two databases [the Ecological Monitoring Program Database (EcMPD) and the Sitewide Ecological Database (SED)] Because extracting data for specific purposes requires a high degree of system-specific knowledge, the two databases are being combined (Kaiser-Hill, 1997d) The new database will allow for multi-user access (with security restrictions) and ease of use with minimal training

5.4 Reporting

A comprehensive ecological management plan (Kaiser-Hill, 1997e) is in place, setting forth the management actions that will be required to preserve the valuable ecological resources present at the Site Site ecologists will update or modify this plan as required by variations in Site conditions, available technology, or changing regulations

The Ecological Monitoring Program issues the following reports annually

- Wildlife survey report (including a status report on the Preble's meadow jumping mouse), and
- Site vegetation report

The overall Site Integrated Weed Control Strategy report (Kaiser-Hill, 1997f) and the Weed Control Strategy and Integrated Treatment Plan (Kaiser-Hill, 1997g) are issued annually to document planned weed control efforts

Additional reports are issued as necessary to document baseline conditions of plant communities or wildlife populations

6.0 INTERACTIONS AMONG MEDIA

Interactions can be identified between groundwater and surface water, between air and soils and among all of these media and ecological conditions both on-Site and potentially at off-Site locations (see Table 7-1 of the *IMP Background Document*). Also, activities upgradient from the Site (e.g., aggregate mining to the west) can influence environmental conditions on the Site and downgradient from it. The monitoring described in the previous sections provides information from which correlations among media can be identified and their effects characterized. For example, surface water quality will be influenced by groundwater perturbations, at least near their interface, and the interaction can be characterized.

Soil chemical and physical characteristics can influence the air, surface water and groundwater quality. While soils are not monitored routinely as part of the Integrated Monitoring Program, many of the interactions are relatively well understood and others are being characterized through special Actinide Migration Studies currently in progress through Site funding. In particular, this study will assist in understanding the importance of soil transport and the influence of water and air on that transport relative to the ultimate fate of radioactive contaminants known to exist in the surficial soils at the Site. This study may point to additional monitoring needs to take the Site to a safe, environmentally sound closure.

Significant habitat effects could accrue from upgradient off-Site activities, as well as on-Site projects, and variations in water supply could affect on-Site and downgradient off-Site habitats. Therefore, to gather data beyond those generated by the monitoring programs described previously, Site personnel collect watershed-level information to assess water availability in the Buffer Zone. Instruments continuously monitor flow at 15 Site locations, and personnel collect seasonal grab samples from seven of those locations for chemical analysis to assess compliance with various regulations (see Table 6-2 in the *IMP Background Document*). In FY99, aquatics sampling on the Site will be performed for the first time in a number of years. The resulting data, and other water quality data, will be analyzed in concert with data being collected off-Site by other stakeholders. These data will supplement understanding of downgradient influences due to Site and upgradient impacts on water quality.

Site-specific correlations between ecological health and water availability have not been quantified, but such interactions have been discussed in the Special Projects working group set up during the current IMP revision process. As more is known about the water balance at the Site, this issue will be revisited so that DQOs could be defined and the need for monitoring assessed.

The IMP working group will continue to meet during the year to discuss new data needs to address our understanding of the interactions among media, especially relating water quality and quantity to the ecological condition of the Site.

1.0 INTRODUCTION

The *Integrated Monitoring Plan* (IMP) revision for fiscal years 1998 and 1999 (FY98/FY99) includes some minor improvements to each media-specific area. Some changes were brought about as a result of an independent review by a subcontractor hired by the Rocky Flats Citizens Advisory Board (CAB). Other changes came about as a result of ongoing discussions by the individual working groups to improve their monitoring programs. Still other changes came from scope modifications directed by the Rocky Flats Environmental Technology Site (RFETS or the Site) management.

In the Ecology area, new monitoring was added for aquatics in streams and ponds. This addition came from a recommendation by the CAB to identify species that could be used as indicators of a release. Aquatic species are such sensitive species as to be indicative of a problem in the drainag systems on Site.

Air Quality Management (AQM) devised and implemented a method for monitoring the radiological impact of environmental restoration (ER) or building decontamination and decommissioning (D&D) or demolition activities that occur through the air pathway. The method involves exchanging filters at key existing ambient samplers on a weekly basis during project activities, performing quick turnaround alpha/beta screens, and, when necessary, expedited isotopic analyses, and tracking project emissions against predefined notification levels.

For Groundwater, the decision was made to include plume degradation evaluation into the IMP. Additionally, the inventory of wells, in Appendix E, that details the wells sampled has been updated to reflect new sampling requirements.

The Surface Water IMP has been updated to include changes in the surface water monitoring programs resulting from the first year's implementation of *Rocky Flats Cleanup Agreement* (RFCA)(DOE et al , 1996) monitoring. The most significant changes involved reorganizing monitoring programs previously categorized as either Industrial Area monitoring or monitoring for industrial area discharges to ponds. Performance monitoring is updated to include new monitoring stations installed for the Walnut Creek source evaluation and administrative transfer of OU2 closure monitoring. Monitoring changes related to the National Pollutant Discharge Elimination System (NPDES) permit renewal options are also addressed. New sections were added for new monitoring of the sanitary collection system (i.e., influent flow and radiological monitoring).

Additionally, the IMP working group decided to add a new subgroup, the Special Projects working group. This group helps to identify and integrate the monitoring that would be required to satisfy the needs of individual projects. This subgroup also took on the issue of soil monitoring and how to include that in the IMP. Soil monitoring is conducted as it relates to specific ER or D&D activities. Furthermore, each media-specific section has developed a Special Project

Template This template is to be used as a guide to develop monitoring data quality objectives (DQOs) for individual projects, which would be consistent with the DQOs for routine monitoring

Integration of Site-wide and project-specific monitoring will occur during the planning of all major new activities, such as ER and D&D projects Kaiser-Hill Company, L L C (Kaiser-Hill) will review all major project plans and evaluate the need for specific environmental monitoring, based on potential release characteristics (e g , constituents and concentrations), potential impact [e g , adherence to regulatory standards, RFCA, and as low as reasonably achievable (ALARA) principles], and existing Site-wide, multi-media monitoring Consideration will be given to data needs before, during, and after a proposed activity Monitoring before a project would assist in defining baseline conditions, characterizing relationships between media, assessing potential impacts to multiple media, and developing designs and controls to eliminate or mitigate impacts Monitoring during and after a project would assist in determining the effectiveness and performance of designs and controls to eliminate or mitigate impacts If additional monitoring is deemed necessary, Kaiser-Hill would work with project personnel to develop appropriate, media-specific DQOs and monitoring specifications Project-specific DQOs will address protection of project personnel, collocated workers, off-Site populations, and the environment, and will complement Site-wide monitoring DQOs Project-specific monitoring plans will be included in separate field sampling plans and/or health and safety plans, and, therefore, will be available for review by the regulatory agencies and other stakeholders Integration of Site-wide and project-specific monitoring could also be the subject of future meetings of the integrated monitoring working group

A key component of the DQO process and the RFETS IMP is data evaluation To be successful, both Site-wide and project-specific monitoring data will need to be continuously evaluated to support the DQO decision rules Decision rules could address baseline definition, relationships between various media, performance and compliance demonstration, and identification of unplanned conditions and trends Actions based on data evaluation are specified by the decision rules Actions also may involve modification of DQOs and monitoring specifications For example, additional data may be required to adequately characterize observed conditions and potential impacts (e g , exceedance of RFCA Tier I and Tier II groundwater action levels), and in some cases, to properly scope a proposed activity (e g , ER and D&D projects, or changes to existing water management schemes) Data evaluation is discussed in the media-specific sections that follow and in RFETS environmental program plans

Data reporting and data exchange were considered during the development of the IMP The data exchange mechanism, which was formalized as a RFCA requirement (Section 207), will provide Site-wide and project-specific monitoring data to all appropriate monitoring entities and regulatory agencies and will allow these groups to evaluate data needs associated with proposed activities (e g , baseline characterization, design, and performance monitoring) Work is progressing on defining the data management tools needed for data exchange and interpretation All entities are involved to ensure that the proper information is conveyed in a timely manner

The plan presented herein should be considered dynamic. The monitoring programs will evolve as further progress is made on Site remediation and closure, as new remediation and closure efforts are planned and initiated that require performance monitoring, as the regulatory setting changes, and as new data become available to improve the statistical design. Such changes will be made by the multi-party working group and documented in updates to this plan. Routine meetings of the working group will be held, and resulting changes will be presented to other stakeholders, including the CAB. Additional work that should be performed is presented below.

- Evaluate detection limits, quality control (QC) specifications, and other aspects not fully specified at this time,
- Finalize process to develop and evaluate monitoring DQOs and plans for new activities, such as ER and D&D projects, including integration of Site-wide and project-specific monitoring,
- Continue to identify integration opportunities between media (see Table 7-1 in Section 7),
- Finalize DQOs for Buffer Zone flow monitoring,
- Develop monitoring DQOs for controlled detention mode of pond operations,
- Continue to evaluate groundwater data regarding Tier I and II exceedances, and modify sampling and analysis accordingly (data review, additional sampling and analysis, and modeling as appropriate), for example
 - Nitrate plume at Solar Ponds,
 - Walnut Creek wells,
 - Wells north of B771/B779 Complex, and
 - Volatile organic compound plume at Property Utilization and Disposal (PU&D) yard,
- Negotiate changes in "National Emission Standards for Emissions of Radionuclides Other Than Radon from DOE Facilities" (Rad NESHAP) monitoring in light of facility D&D [i.e., use of ambient monitoring to demonstrate compliance with National Emission Standards for Hazardous Air Pollutants (NESHAP) standards],
- Solicit broader stakeholder input (e.g., present plan and modifications to interested stakeholder groups),

- Convene integrated monitoring working group routinely (e g , semiannually), and
- Complete development of mechanism to exchange data among monitoring entities and with other stakeholders

1.1 Background

Soon after Kaiser-Hill became the Integrating Management Contractor at the RFETS, Kaiser-Hill undertook a structured, comprehensive, reevaluation of all environmental monitoring programs. The objective of this effort was to develop specifications for monitoring utilizing the U S Environmental Protection Agency's (EPA's) established DQO process. The process involved the Department of Energy (DOE), EPA and Colorado Department of Public Health and Environment (CDPHE) (state) regulators, the cities of Broomfield and Westminster, and the Kaiser-Hill team. The effort was intended to identify any unnecessary monitoring and existing weaknesses in the monitoring programs, and to ensure protective and compliant programs. Using the consensus specifications (DQOs), an optimal data collection design was determined. This approach demonstrates compliance with the myriad of federal and state regulations and DOE Orders, and supports the decisions that must be made to protect human health and the environment with an acceptable degree of certainty. The monitoring programs of the regulators and cities were included and also modified to develop an integrated, multi-party Site monitoring program. The development and maintenance of this integrated program became a requirement of the RFCA issued on July 19, 1996¹. The *Integrated Monitoring Plan* is a result of the process described above.

The DQO process is a structured decision-making process that requires the identification of and agreement on decisions for which data are required, and results in the full set of specifications needed to develop a protective and compliant monitoring program (i e , qualitative and quantitative statements that specify the type, quality, and quantity of the data required to support decision making). The formal DQO process is documented in two EPA documents (EPA, 1993a, EPA, 1993b). In September 1994, DOE institutionalized the DQO process for environmental data collection activities. This was implemented to balance DOE's environmental sampling and

¹ RFCA Part 21 Sections 267 and 268 state "In consultation with CDPHE and EPA, DOE shall establish an IM that effectively collects and reports the data required to ensure the protection of human health and the environment consistent with the Preamble, compliance with this Agreement, laws and regulation, and the effective management of RFETS's resources. The IMP will be jointly evaluated for adequacy on an annual basis, based on previous monitoring results, changed conditions, planned activities and public input. Changes to the IMP will be made with the approval of EPA and CDPHE. Disagreements regarding any modifications to the IMP will be subject to the dispute resolution process described in Subpart 15B or E, as appropriate."

"All Parties shall make available to each other and the public results of sampling, tests, or other data with respect to the implementation of this Agreement as specified in the IMP or appropriate sampling and analysis plan. If quality assurance is not completed within the time frames specified in the IMP or appropriate sampling and analysis plan, raw data or results shall be submitted upon the request of EPA or CDPHE. In addition, quality assured data or results shall be submitted as soon as they become available."

analysis costs with the need for sound environmental data that address regulatory requirements and stakeholder's concerns. Specific steps in the DQO process include

- Identify and define problem(s) to be solved,
- Identify decision(s) to be made relative to the problem,
- Identify inputs to the decision (data needed to make decision),
- Define study boundaries/scope of problem and decision,
- Develop decision rule(s) [IF/THEN action statement(s)],
- Specify limits on decision errors (acceptable types and degrees of uncertainty), and
- Develop and optimize design for obtaining data

The goal of using this approach was to reevaluate the basis and focus of existing programs, increase the defensibility of Site monitoring, and incorporate regulatory changes (e.g., water quality standards and cleanup levels) associated with RFCA. The RFCA requirements have been incorporated into the DQOs.

Implementation of the DQO process forces data suppliers and data users to consider the following questions

- What decision has to be made?
- What type and quality of data are required to support the decision?
- Why are new data needed for the decision?
- How will new data be used to make the decision?

DOE and Kaiser-Hill recognized that the Site could no longer have separate, non-integrated sampling and analysis activities performed by various entities at the Site (e.g., Environmental Restoration and Environmental Protection), or between the Site, the cities, CDPHE, and EPA Region VIII. DOE and Kaiser-Hill also realized that they should not work alone, therefore, an integrated monitoring working group was formed with representatives from EPA, CDPHE, and the cities of Broomfield, Northglenn, Arvada, and Westminster to develop consensus on what data were needed and how data would be used, and to develop sampling and analysis plans based on these specifications. The responsibility for data generation was then spread across these entities in a logical way. In developing the requirements for an integrated monitoring plan, the decisions and multimedia data requirements associated with the Resource Conservation and

Recovery Act (RCRA), the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the Clean Air Act (CAA), the Clean Water Act (CWA), the Colorado Water Quality Control Commission (CWQCC) standards, natural resource management regulations, Site-specific cleanup agreements (e g , the *Industrial Area Interim Measures/Interim Remedial Action Decision Document*), and several DOE Orders were considered. After data requirements to support each of the desired decisions were identified, data collection was streamlined by looking for opportunities to use measurements for more than one decision.

To accomplish the work associated with developing an integrated monitoring plan, four medium-specific DQO working groups (i e , surface water, groundwater, air, and ecological resources) were established. Each group met regularly to work through the DQO process for each decision that required monitoring data. In addition, all four groups met together to discuss data needs across media, share progress, ensure consistency, and identify problems. DQO facilitators and statisticians, sponsored in part by DOE Headquarters, assisted the integrated monitoring working group in developing the DQOs, evaluating the adequacy of existing designs, and developing new sampling and analysis plans. The results of these efforts represent a multi-party consensus agreement and are documented in this document by environmental media. Integration was achieved between monitoring entities, regulatory programs, and environmental media. Interactions between media are discussed in Section 7.0 of this *IMP Background Document*.

This document covers all the environmental monitoring conducted by DOE and the Kaiser-Hill team, as well as monitoring conducted by CDPHE and the cities where interface and integration opportunities exist. Other monitoring conducted by CDPHE and the cities is related to the Site, but does not present integration opportunities (e g , monitoring of area reservoirs conducted by the cities and spot checks conducted by CDPHE).

2.0 SURFACE WATER

2.1 Introduction

This chapter of the *Integrated Monitoring Plan (IMP) Background Document* is written so that it can be used in two different documents, as needed. The Site-wide plan may be in draft or under negotiation at times when Rocky Mountain Remediation Services, L L C (RMRS) must demonstrate and document management control of their work. Thus, two separate documents are occasionally required, but the two documents must have the identical negotiated text. This plan has been written to accommodate this need.

2.1.1 Summary of Monitoring Objectives

This document describes surface water monitoring objectives to be implemented for fiscal years 1998 and 1999 (FY98/FY99). The monitoring described herein integrates all surface water monitoring across the Rocky Flats Environmental Technology Site (RFETS or the Site) (see Figure 2-1), including much of the Site monitoring performed by the cities and the state.

The data quality objective (DQO) process was used to determine necessary and sufficient monitoring requirements. The process yielded over 20 data-driven decisions. Some decisions need a higher priority than others, and some need greater confidence than others. The DQO process has produced descriptions that expose the strengths and weaknesses of each data-driven decision, and the value of the data (resources required) in making each decision. Management decisions often must be made on the basis of incomplete information. The individual DQO sections of this document help management to establish funding priorities for surface water monitoring objectives.

Surface water monitoring objectives (a.k.a. decision rules under the DQO process) have been organized in a roughly upstream-to-downstream direction, beginning with process discharges within the Industrial Area and ending at the drinking water reservoirs downstream, as depicted in Figure 2-2. These monitoring objectives are summarized in the following paragraphs and are discussed in detail in the remainder of this section.

Monitoring objectives that do not fit into the upstream-to-downstream sequence are discussed in Section 2.2, Site-Wide Monitoring Objectives. For example, safe operation of the dams is dependent on some monitoring to avoid breaching a dam. This monitoring objective is placed first (Section 2.2.1), in recognition of its unique importance in avoiding imminent danger to life and health (IDLH) situations. Another monitoring objective is Source Location Monitoring, which is covered in Section 2.2.2, to locate a source of contamination detected by other monitoring objectives.

Figure 2-1 Conceptual Sketch of Major Site Surface Water Features

¹ Controlled detention is a strategy for Site pond operations that would allow continuous discharge of water from the terminal ponds under carefully controlled conditions

² System designed to capture a contaminated subsurface plume on the north slope of the Solar Pond Area of the Industrial Area

Figure 2-2. Conceptual Model of Site Monitoring Objectives

Additionally, the RFCA specifies monitoring for the upstream reaches of Site drainages (above the ponds) and specifies action levels for contaminants (Action Levels and Standards Framework [ALF]). This Stream Segment 5/point of evaluation (POE) monitoring is addressed in Section 2 4 2

Terminal detention pond discharges and surface water leaving the Site must also be monitored. Predischarge monitoring of terminal ponds occurs prior to controlled discharges (Section 2 5 1). The Site must also monitor at points of compliance (POCs) below the terminal ponds to protect state stream standards in Segment 4 (Section 2 5 2), as specified in the RFCA. In addition, there are RFCA POCs that are monitored at the Site boundary at Indiana Street (Section 2 5 2).

The State of Colorado and downstream communities are concerned that the water quality in downstream waters might be degraded by Site discharges. Section 2.6 addresses off-Site monitoring needs. These data are used to make decisions regarding use of the water for drinking and irrigation and for compensatory actions such as providing alternate water sources and reservoirs.

Section 7.0 of this *IMP Background Document* addresses the interfaces between surface water and other media: soil, groundwater, air, and ecology. For example, groundwater and soil could conceivably contaminate surface water, and surface water could contaminate habitats of endangered species. Monitoring requirements to evaluate the interactions between media are specified in the Groundwater Monitoring Section 3.0.

2.1.2 Geologic and Hydrologic Setting

This section is included only as an introduction to the Site for the lay public not already familiar with the Site. This section contains no monitoring requirements or other commitments or agreements between the parties. This section contains no material that affects the interpretation of the rest of the document.

Geographically, the Site surface waters are bounded

- Upstream by the West Interceptor Ditch (McKay Bypass),
- On the south by the South Interceptor Ditch (SID) or by Woman Creek, subject to discussion and context,
- On the north by the landfill drainage, and
- On the downstream end by Great Western Reservoir and Standley Lake or by Stream Segment (Segment) 1 of Big Dry Creek, subject to discussion and context

These features are shown in Figure 2-1 and Figure 2-3. A detailed discussion of Site geology and hydrology is presented in Appendix C to Section 3.0 of this IMP.

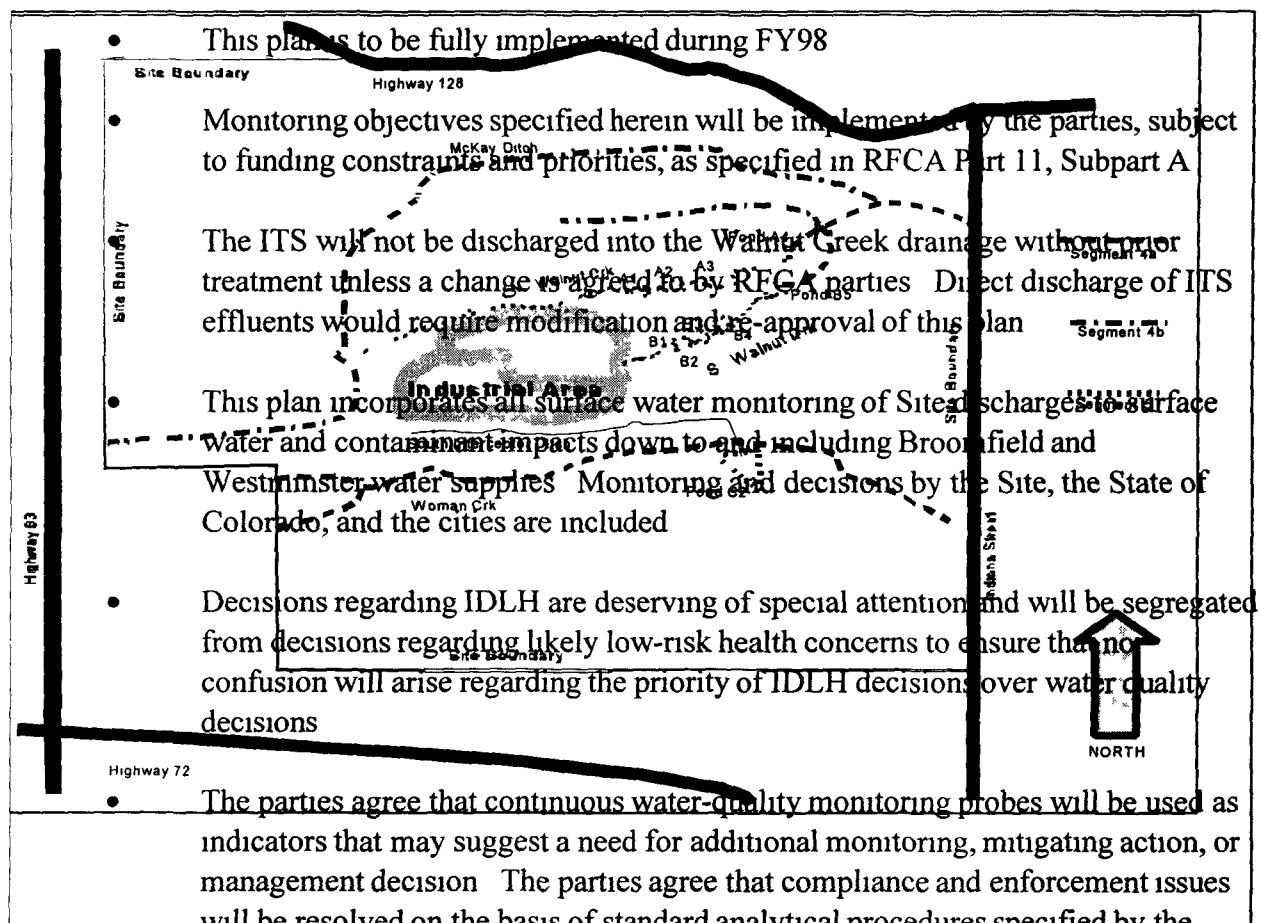

The stream drainages leading off Site are Walnut Creek, Woman Creek, and Rock Creek. The figures illustrate the first two drainages and their tributaries. North Walnut Creek and South Walnut Creek flow through the A and B series ponds, respectively. The Colorado Water Quality Control Commission (CWQCC) has designated the portion of these drainages from Ponds A4 and B5 to Indiana Street as Stream Segment (Segment) 4b. Tributaries to the A and B terminal ponds, and Pond C2 itself, are designated as Stream Segment 5. The South Interceptor Ditch and Ponds A1, A2, B1, and B2 have not been designated as waters of the State. These stream segment designations are best illustrated in Figure 2-3.

2.1.3 Assumptions

The Surface Water IMP Team had to make some assumptions in order to limit the monitoring program to address reasonable concerns. The alternative was to monitor for all possible Site conditions, contaminants, and practices, which would have been an inefficient use of tax dollars. The Team's planning assumptions are presented below. These assumptions may not continue to be true in the future in all cases, and this document does not constitute agreement between the parties that these assumptions will be maintained. However, if an assumption becomes invalid during the effective period of this plan, then some of the monitoring that was excluded on the basis of that assumption should be reconsidered and possibly implemented in future years.

- Deviation from these assumptions requires prior approval of the U.S. Environmental Protection Agency (EPA), Colorado Department of Public Health and Environment (CDPHE), and the Department of Energy (DOE), as required in RFCA Part 23, paragraph 267.

Figure 2-3. Sketch of Stream Segments 4a, 4b, and 5

Best Available Copy

4 liters (L)], weather conditions, work schedules, sample preservation, potential loss of data, regulatory reporting schedules, and other concerns

- Non-Sufficient Quantity (NSQ) If sample accumulation is terminated for cause, and sample volume is inadequate for routine lab analyses, then no analyses are required, and the sample will not be used in the computation of a 30-day moving average. For example, routine lab analysis for plutonium (Pu), americium (Am), and tritium requires 4.5L. Therefore, samples of less than 4.5L may be discarded and not used in the computation and evaluation of compliance parameters, but must be reported. This requirement may be referred to as the NSQ requirement regarding insufficient quantity of sample.
- The 30-day moving averages will be computed twice each month within 5 working days of the 15th day and the last day of the month for sample results received between the reporting dates and reported per the RFCA ALF.
- Where there is no significant flow, there may be no samples completed within a 30-day period. However, flow-paced sampling will continue during dry periods, even though flows may be so low that it may take longer than 30 days to fill the sample carboy.
- If no samples are taken during a 30-day interval, then no sample result will be available for use in the computation of a 30-day moving average, and no such average will be reported for that period.
- All samples taken for RFCA monitoring under this plan must be reported, even if they are not analyzed, and the reason for not analyzing (e.g., NSQ) must be reported.
- All monitoring data acquired under the same procedural controls as used for RFCA monitoring are actionable³ under RFCA and applicable regulations, even though it may not have been specifically identified as an analyte of interest (AoI) in Tables A-26 and A-27 in Appendix A to this section.
- Many areas of the Site are linked by the flow of water within and above the ground surface in an upstream-to-downstream direction. Contaminants monitored in one area may have originated in an upstream area.

³ The term "enforceable" has been reserved for Segment 4 standards, as opposed to Segment 5 action levels. The term "actionable" is intended here to include enforcement actions, actions taken in response to action level exceedances, and any other action required under RFCA in response to monitoring data.

- These monitoring objectives are driven by both federal and state regulations which include Site-specific CWA requirements and underlying CWQCC standards and the Colorado Water Quality Control Act
- Each monitoring objective that requires comparison to baseline assumes that establishment of baseline will be performed before decisions are made on the basis of the data Each monitoring objective that specifies decisions based on statistical tests assumes that variability of data will be established before decisions are made on the basis of the data

2.1.4 Outstanding Issues

- As of this revision, the NPDES permit has not been re-issued When the new permit is approved, the IMP Surface Water Working Group (SWWG) will review permit requirements for impacts on monitoring
- The Site operators request to change pond operations protocol from batch discharge to controlled detention for off-Site release of surface waters and related impacts on monitoring are also unresolved
- Terminal ponds will continue to be operated in a batch mode throughout FY98 until agreed on by all parties
- A detailed summary of ongoing Industrial Area decontamination and decommissioning (D&D) monitoring is not part of the IMP or the *IMP Background Document* This information should be reported in an annual summary to accompany the IMP and the IMP Background Document This summary should include a review of performance monitoring and any monitoring of routine sanitary waste streams

2.1.5 Quality Assurance

Sampling and analysis of Site surface water is controlled by Standard Operating Procedures, the RMRS *Quality Assurance Program Plan*, the *Site Quality Assurance Manual*, and Analytical Services' *Statement of Work for Analytical Measurements, General Laboratory Requirements* The *Statement of Work for Analytical Measurements, General Laboratory Requirements* presents the approved analytical methods, hold times, detection limits and laboratory data reporting protocol Sample sizes (number of independent samples analyzed) for FY98 were determined by the NPDES permit in some cases and by desired confidence intervals, subject to funding limitations, in other cases For additional details, such as requirements for blanks and duplicate samples, refer to the following plans and procedures

- *Statement of Work for Analytical Measurements, General Laboratory Requirements, Module GR01-A* Kaiser-Hill Company, L L C , Golden, Colorado, December 10, 1996
- *Site Quality Assurance Manual, Rocky Flats Plant* Rocky Flats Environmental Technology Site, Golden, Colorado, 1996
- *Quality Assurance Program Plan Manual No 95-QAPP-001, Rev 0, 10/4/95* Rocky Mountain Remediation Services, L L C , Golden, Colorado, 1995
- *EMD Operating Procedures Volume I, Field Operations, Manual No 5-21000-OPS-FO* EG&G Rocky Flats, Inc , Rocky Flats Plant, Golden, Colorado, 1992
- *EMD Operating Procedures Volume IV, Surface Water, Manual No 5-21000-OPS-SW* EG&G Rocky Flats, Inc , Rocky Flats Plant, Golden, Colorado, 1992

2.1.6 Reporting

Data specified in the surface water monitoring objectives are used in decision making. Many of the data are not routinely reported other than to the decision-maker(s) for a particular decision. Such data remain available in the Site Soil and Water Database (SWD) for subsequent queries (Secondary data usage is quite common). Some typical examples of data usage are described below. (This is not a complete list.)

- IDLH data are used to determine when valves and flood gates should be opened and closed. Some of these data may be reported verbally to the DOE, Rocky Flats Field Office (RFFO) and regulators during the decision-making process, but no formal report of pond levels, valve positions, and piezometer readings is produced as a regulatory report.
- If data helped to locate a new contaminant source, then the source and data would be reported for appropriate management action.
- *Ad hoc* monitoring requested by on-Site parties is reported to the requestor.
- The results of monitoring for correlation of Pu with particulates could be published in a letter report, at the discretion of the Site.
- The NSD monitoring would be reported internally to initiate action if a new contaminant source were detected, but no public or regulatory report would be routinely produced.

- The disposition of internal waste streams and incidental waters is based on data-driven decisions. The data are recorded and reported to the decision maker, with an annual summary of routine internal waste streams provided to the EPA.

There are a few routine reports prepared for surface water data. Current reports are

- NPDES monitoring data are reported in a Discharge Monitoring Report (DMR) each month to EPA,
- CDPHE routinely reports predischARGE and community-assurance monitoring results to the Site and cities,
- Exceedance of RFCA standards and action levels must be reported to both EPA and CDPHE, and
- Many of the surface water data are summarized and reported at the Quarterly Information Exchange Meetings.

2.2 Site-Wide Monitoring Objectives

The monitoring objectives in this IMP are generally presented in an upstream-to-downstream order. This section deals with monitoring objectives that cannot be ordered in that way. This section also deals with cross-cutting monitoring objectives such as safe operation of the dams (Section 2.2.1), location of contaminant sources wherever they may occur (Section 2.2.2), special request (*ad hoc*) monitoring (Section 2.2.3), and the use of operational indicators for Pu to describe actinide transport and to design and implement pond operations (Section 2.2.4). None of this monitoring is confined to a single geographical area of the Site. Figure 2-4 shows the locations of specific monitoring locations referenced under each objective. In the interest of fiscal and operational efficiency, many of these locations collect data to support multiple monitoring objectives. The location code shown is the code used in the Site Soil and Water Database (SWD).

2.2.1 IDLH Decision Monitoring

This IDLH section uses the term “action level” in reference to dam operations. This is an entirely different usage unrelated to the RFCA Action Levels and Standards Framework (ALF) discussed elsewhere in this document.

The Site has a network of detention ponds with earthen dams (Figure 2-4). Failure of an earthen dam would present an IDLH. Safety and health professionals often refer to such conditions as IDLH conditions. The Site has several ponds formed by dams that can hold a limited amount of water safely. Water may be discharged from these ponds through the outlet works or by pumping. Water does not normally overtop the dams, which are all of earthen construction and would be damaged and could fail under those conditions. Heavy rain or snow melt can challenge the capacity of the ponds faster than the ponds can be predischarged, monitored and subsequently batch discharged.

Problem Statement

If water levels rise above safety limits that preserve dam integrity, then ponds must be discharged to prevent overflow or breaching.⁴ The risk to the public and environment is far greater from a dam breach than from the normally low levels of contaminants that might be found in pond waters.

Problem Scope

⁴ Maximum discharge rate for earthen dams is one foot per day to achieve drawdown without inducing sloughing of the saturated sides of the dam.

The actual decision process for managing pond operations and conducting pond and dam monitoring activities is too complex to be treated in this document. Detailed information

Figure 2-4 here

can be found in the *Pond Operations Plan* (POps)(Kaiser-Hill et al , 1996), and the *Action Level Response Plan for Dams A-4, B-5, or C-2* (EG&G, 1995) The following *generalized decisions* must be made on a continuous basis for Pond A4 Similar decisions are made for Ponds A3, B5, and C2 A series of simultaneous equations are solved via an expert system framework to consider actions associated with modeled action levels

Information Types and Frequency

The decision factors include safe pond capacity, actual pond elevation, current and projected flow rates into and out of the ponds, and several indicators of dam integrity, such as piezometer readings, inclinometer readings, and cracks or sloughs of embankment material The information needs are as follows

- Pond inflow rates into Ponds A3, A4, B5, and C2 (must be continuously monitored for daily to hourly averages with instantaneous measurement capability)⁵
- Pond elevation for Ponds A3, A4, B5, and C2 (must be continuously monitored for daily to hourly averages with instantaneous measurement capability)
- Measurements from piezometers in dams (indication of water pore pressure in dam structures)
- Daily to hourly visual inspections of dam integrity
- Results from the expert system that rates the above inputs to determine whether to release water from a dam despite water quality [Note *Pond Operations Plan* (Kaiser-Hill et al , 1996) details decision tree that describes this logic]
- Pond discharge rates (pumped or through outlets, daily to hourly averages with instantaneous measurement capability)
- Weather prediction (affects the weighting factors in the expert system)
- Biannual dam inspections
- Annual Federal Energy Regulatory Commission (FERC) inspection

⁵ Critical measurements, such as pond inflow rates and elevations, require hourly monitoring capability, even though daily monitoring may be adequate for a portion of the year For example, during FY 1996 (FY96), hourly monitoring was actually used for 85 days during the year

- Crest monument movement monitoring [required by *Code of Colorado Regulations* (CCR) for dams]
- Inclinator monitoring (required by CCR for dams)

Boundaries

<i>Spatial</i>	Flow in streams upgradient to Ponds A3, A4, B5, and C2 is used in decision making. Each individual dam and the water volumes in each pond is included in decision making. The only dams that are normally operated to contain or release water off Site are A4, B5, and C2 in the North Walnut Creek, South Walnut Creek, and Woman Creek drainages, respectively (Woman Creek normally flows around Pond C2, through an artificial diversion. However, Pond C2 is directly in the natural drainage of Woman Creek and may receive overflow from Woman Creek during extreme flood conditions.) Pond A3 may also be included in this list as a terminal pond under some conditions, such as during construction activities in Pond A4.
<i>Temporal</i>	Information is collected at varying intervals based on the pond conditions and rate of change of the specific parameter. Daily or more frequent dam piezometer data, hourly in-flow data, and hourly to daily pond level data are all transmitted by telemetry. Most decisions are made Monday through Friday on a daily basis, however, during a crisis situation, hourly decisions may be made seven days a week. The Site also maintains instantaneous measurement capability for all telemetry data.

Decision Statements

IF	Water quality analytical results meet all applicable standards to protect downstream water users, and dam is at pond operations Action Level 3 or less [determined by piezometer readings (water level in dam structure), dam inspections, pool level, and inflow data]—
THEN	The Site will discharge water from the pond
IF	A pond reaches Action Level 4 (i.e., exceeds its safe capacity based on data including piezometer readings, dam inspections, pool level, and inflow data)—
THEN	The Site will release water (without waiting for analytical results) from the pond at a drawdown rate of one foot per day and notify the Colorado State Engineer and other specified agencies

- IF A pond reaches Action Level 5 [spillway overflow occurring or overtopping expected and/or breaching possible based on data including piezometer and inclinometer (measures the change in a slope, providing early warning of a potential dam failure) readings, dam inspections, pool level, inflow data]—
- THEN The Site will release water (without waiting for analytical results) from the pond at a drawdown rate of 2 feet per day Notifications to Colorado State Engineer and other agencies are required
- IF Routine or emergency dam inspections, inclinometer readings, piezometer readings, and/or other monitoring activities reveal changed conditions affecting the structural integrity of a dam—
- THEN The Site will notify the Colorado State Engineer and other agencies, as required by the CCR (2 CCR 402-1, Rules 14 and 15) and *Colorado Revised Statutes* (CRS) (CRS 37-87-102 through 115), and develop alternatives, as necessary and appropriate, to correct the identified problem

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The Surface Water IMP Team determines the frequency and type of monitoring specified as appropriate to identify any structural problems in a timely manner consistent with standard industry practices and applicable regulations
- Acceptable Decision Error Rates for Statistical Sampling Design
 - Does not apply

Monitoring Requirements

Monitoring requirements determined to safely operate the dams are presented in Table 2-1

Table 2-1
Monitoring Requirements (Number of Samples/Analyses)
for Safe Operation of Dams

Data Types Monitored	Pond											
	A1	A2	A3	A4	B1	B2	B3	B4	B5	C1	C2	Landfill
Inflow rate (telemetry measurement)	—	—	9/day [SW093]	9/day [GS12]	—	—	—	—	9/day [GS09]	—	9/day [SW027]	—
Inflow rate (field measurement)	1/week	1/week	1/day	1/day	1/week	1/week	—	—	1/day	—	1/day	—
Discharge rate (telemetry measurement)	—	—	9/day [GS12]	9/day [GS11]	—	—	—	—	9/day [GS08]	—	9/day [GS31]	—
Discharge rate (field measurement during discharge)	4/day	4/day	4/day	4/day	4/day	4/day	—	—	4/day	—	4/day	4/day
Pond elevation (telemetry measurement)	—	—	9/day	9/day	—	—	—	—	9/day	—	9/day	—
Pond elevation (field measurement)	1/week	1/week	3/week	3/week	1/week	1/week	—	—	3/week	—	3/week	1/week
Piezometers (telemetry measurement)	—	—	3/day	3/day	—	—	—	—	3/day	—	3/day	—
Piezometers (field measurement)	—	—	1/week	1/week	1/week	—	1/week	—	1/week	—	1/week	1/week
Routine dam inspection	1/week	1/week	1/week	1/week	1/week	1/week	1/week	1/week	1/week	1/week	1/week	1/week
Biannual detailed dam inspection	2/year	2/year	2/year	2/year	2/year	2/year	2/year	2/year	2/year	2/year	2/year	2/year
Annual FERC and DOE dam inspection	1/year	1/year	1/year	1/year	1/year	1/year	1/year	1/year	1/year	1/year	1/year	1/year
Inclinometer (field measurement)	—	—	—	4/year	—	—	—	—	4/year	—	4/year	—
Crest monument movement (field measurement)	—	—	—	4/year	—	—	—	—	4/year	—	4/year	—
Use of computer expert system to predict pond filling and/or discharge events (using data from telemetry and field measurement)	1/week	1/week	1/week	1/ week	1/week	1/week	—	—	1/ week	—	1/ week	1/week

Notes

Where nine measurements per day are indicated, this is the estimated average of critical measurements that are actually targeted. This varies from daily to hourly, and the hourly capability is required for 50-100 days per year. Instantaneous measurement capability is also desired for telemetry data.

— = Not applicable
DOE = Department of Energy
FERC = Federal Energy Regulatory Commission
Specific automated gauging station locations shown as [GS12] for example

2.2.2 Source Location Monitoring

As used in this section a “source” is a contaminant source. The term “new source” as used in this section means any source that has not yet been located, halted, mitigated, quantified, or corrected. The parties intend that this decision rule will initiate appropriate action, even though a source may exist prior to the implementation of this IMP.⁶

Problem Statement

When new contaminant sources are detected by surface water monitoring within the Industrial Area, at NSD locations, at POEs, at POCs, or in the downstream reservoirs, additional monitoring may be required to identify⁷ the source and evaluate for mitigating action pursuant to the RFCA ALF. The Source Location Monitoring objective is used to locate the source of contamination when a new source of contamination is detected.⁸

Information Types and Frequency

Analyte suites under this decision rule are determined based on the contaminant of current concern that has caused the exceedance, or related indicators. The information types are entirely dependent on the results of other monitoring objectives under which the source was detected. The analyte suites are limited to parameters which will aid in the identification and evaluation of a contaminant source.

Boundaries

Spatial Source location monitoring may be implemented anywhere within the Site surface water drainage area (especially within the Industrial Area) where a new contaminant source or exceedance is detected. The distribution of monitoring points is determined by the details of the specific source evaluation to determine source location and to efficiently utilize resources. For example, if monitoring (just outside the Industrial Area) for NSD suggests a new source within the Industrial Area, then portable sampling equipment may be installed within the Industrial Area to locate the source. And, if monitoring for compliance in Segment 4 suggests a new source, then monitoring to identify the source may begin in Segment 5.

⁶ A decision rule under the DQO process links Site environmental data with operational and regulatory decisions.

⁷ Note that the term “identify” is used here to mean “locate.” Characterization is also implied.

⁸ The various monitoring objectives might “detect” a new source through an increase in baseline or exceedance of an action level, standard, permit limitation, etc., depending on the monitoring objective under which the potential new source was detected.

Temporal Source location monitoring should begin as soon as practical after source detection and continue until the source is identified and evaluated or is no longer detected. The number of samples will be based on the status of the source evaluation, taking into account, but not limited to, weather conditions, water availability, and process knowledge.

Decision Statement

IF A new contaminant source is identified by any monitoring objective—

THEN The Site will take appropriate and immediate action to halt or mitigate, locate and quantify the source, and implement mitigating action pursuant to the RFCA ALF

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - This decision rule is only invoked when new sources are detected under other monitoring objectives. Comprehensive monitoring for *detection* of new sources is an issue for other monitoring objectives. Comprehensiveness and representativeness may be developed for specific instances of source location actions.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - A generally applicable statistical sampling design has not been used.

Monitoring Requirements

The need for source location monitoring stations is dependent on the results of monitoring under other objectives. Therefore, it is impossible to estimate the exact monitoring targets under the Source Location Monitoring objective for each year. In FY97, Pu water-quality exceedances were detected at GS03, GS10, and SW093. As part of the source evaluation, eight source location monitoring stations may be operated in FY98. For planning purposes, Table 2-2 contains estimated analyses supporting the FY98 source evaluations, that would be performed at multiple source location stations, to locate and characterize the sources contributing to any of the exceedances.

2.2.3 Ad Hoc Monitoring

The Site often monitors surface waters on an *ad hoc* basis for a variety of reasons. This monitoring may or may not be used in decision-making processes, but it has been frequently requested by DOE, RFFO, cities, agencies, building managers, and the WWTP in the past. The Surface Water IMP Team anticipates that the DOE, RFFO will continue to request such *ad hoc*

Table 2-2

monitoring in the future, regardless of whether funding is allocated for that purpose. This monitoring will not always require sample analyses. In some cases only flow alarms will be needed. Some examples that may warrant *ad hoc* monitoring include:

- Major precipitation events that disrupt routine pond predischage monitoring and discharge schedules,
- Community assurance monitoring at the request of downstream cities and the DOE, RFFO,
- Unanticipated changes in regulatory permits, agreements, or funding,
- Anticipated but unfunded changes in permits or agreements,
- Construction projects,
- Spill events, or
- Operational monitoring (i.e. footing drains, septic lift stations)

The monitoring estimates in Table 2-3 are based on fiscal years 1995-1996 (FY95/FY96) actual monitoring, with spring 1995 sampling taken at 70% of actual to correct for the unusually high

monitoring requirements during April, May, and June of 1995. Analytes listed are typical of current and past monitoring, but actual monitoring for future periods will certainly differ from this estimate.

2.2.4 Monitoring for Correlation of Plutonium with TSS⁹

The Site intends to move toward controlled detention operation of the ponds in FY98. The controlled detention design basis indicator for Pu will be at first total suspended solids (TSS), which historical stormwater data have shown to be correlated with Pu activity (Gilbert, 1987) at several locations. This correlation was a primary assumption in the design basis for the controlled detention *Pond Operations Plan*¹⁰ (Kaiser-Hill et al., 1996). To test these hypotheses, it is desired that samples be analyzed for Pu and TSS at selected monitoring locations to be used operationally for controlled detention discharge of the ponds in the future. This analysis may quantify the correlation between Pu and TSS.

Problem Statement

This monitoring objective is intended to establish the relationship of Pu concentrations with several indicator parameters, such as TSS, turbidity, or flow rate. The determination of relationships between Pu and indicator parameters will support future pond operations, investigations into actinide transport, and management decision making.

The design basis for controlled detention is that Pu can be estimated as a function of TSS. Under controlled detention, the operational indicator might be turbidity, flow, or other indicators that can be monitored in real time. This section also addresses the correlation of Pu with other parameters that can be monitored in real time for operational decision making. TSS requires time for a laboratory analysis, so although it may provide a satisfactory design basis, it cannot be used as an operational indicator.

This section specifies data needed to develop deterministic regression models for estimating Pu concentrations in Segment 4 (below the terminal ponds) on the basis of TSS or turbidity data from Segment 5 (above the terminal ponds) and from within the Industrial Area. This section will also provide data for models that could estimate the magnitude of Pu contaminant sources within the Industrial Area on the basis of data from Segments 4 and 5. With respect to surface water, research indicates a relationship may exist between the amount of Pu activity and the amount of TSS in the water. Radionuclides, including Pu, tend to associate with particulate materials. When particles are carried in surface water runoff, radionuclides attached to the particles are transported as well. Therefore, measuring the amount of TSS in runoff from a specific drainage area

⁹ Note: This section on the relationship of Pu with suspended particulates is *not complete*. The material in this section has been retained for future use, but several fundamental issues must be resolved, and a major rewrite will almost certainly be required before indicator monitoring should begin. Consensus on this section may be difficult to achieve due to the concerns surrounding controlled detention operation of Site ponds. However, all members of the Surface Water IMP Team have agreed that decisions regarding controlled detention should be well-informed decisions based on monitoring data such as is identified in this section.

¹⁰ Pu is transported primarily on particulates in stormwater.

can provide a characteristic ratio of Pu to TSS for that basin and insight into the amount of Pu activity being transported in the water

If an initial correlation between Pu activity and TSS is determined for a drainage basin, it would prove useful for monitoring future cleanup and containment of Pu within that area. For example, removing a source of Pu-contaminated sediments from a watershed would result in less transport of Pu from the basin, and, barring the creation of new sources of contaminated suspended sediments, the Pu activity associated with a given TSS concentration would also have been lowered. Therefore, a decrease in the ratio of Pu activity to TSS would be indicative of the effectiveness of the source removal. In contrast, an increased ratio might indicate a new source of Pu.

Data from this monitoring would also support evaluations of the impact of D&D and watershed improvement activities.

Information Types and Frequency

To evaluate the correlation between TSS, turbidity, and flow with Pu, monitoring at any three stations would suffice, but six stations should be monitored in case some do not correlate well. Since Pu is already monitored at terminal pond outfalls (POCs) and at the Industrial Area boundary (POE and NSD locations), flow, TSS, and turbidity (turbidity monitored real time) will also be monitored at these eight stations.

To evaluate the predictive capability of the real-time flow and turbidity parameters, the Site must monitor these parameters at locations most likely to be predictive and far enough upstream to provide at least 2 hours of warning before an exceedance could occur in Segment 4 (at a POC). These stations include POEs GS10, SW093, and SW027 and NSDs SW022 and SW091. Each of these stations will be equipped with real-time, water-quality probes to continuously monitor turbidity.

Ideally, TSS would be analyzed for all samples collected at the above locations. However, sampling protocols for these stations (detailed in Sections 2.4.1, 2.4.2, and 2.5.2) often result in composite samples that are collected over periods exceeding the 7-day hold time for TSS analyses. Therefore, TSS cannot be analyzed for all composite samples but will be analyzed when possible. For reference, NSD locations collect composite samples during singular runoff events, while POCs and POEs collect composite samples continuously during all flows.

Boundaries

Spatial Data may be acquired as far upstream as Segment 5 or even within the Industrial Area to predict Pu as far downstream as the reservoirs.

Temporal: No known constraints

Decision Statement

IF The correlation between total Pu activity and TSS exceeds 0.80 at three or more monitoring location pairs¹¹ for a period of six months or more, including peak spring runoff events and base flow, (Gilbert, 1987) (see reference)—

THEN Knowledge of this correlation is shared with the Actinide Migration Studies Team for further investigation. The Actinide Migration Studies Team will work with the RFCA monitoring team to determine whether the relationship between Pu and TSS is significant enough to be used as a design basis for operation of the ponds, and the Site may then attempt to establish the specific numerical values needed to design protective pond operations and structures. Results of these studies will be presented to stakeholders for consideration as a basis for operations.

An identical decision may be made for a relationship between Pu activity and turbidity, or a combination of TSS and turbidity, or other indicators. Note that use of the relationship between Pu and suspended particulates as a design basis for pond operations would not necessarily preclude real-time monitoring, short-term storage and screening, alternative routing of pond water, or other protective engineering features.

IF The Site can demonstrate mathematically that a regression model of discharged Pu as a function of turbidity and/or flow and/or another real-time parameter¹² would provide at least 4 hours of warning before discharged Pu would exceed the applicable RFCA standard so that outlet works could be closed or so that the effluent could be redirected,

AND IF A controlled detention terminal pond can be isolated from the WWTP and ITS—

THEN The parties to this document will actively support a full one-year trial of controlled detention for that terminal pond, subject to approval of the operational plan.

¹¹ Monitoring location pairs. Theoretically, monitoring for TSS at GS10 (east edge of Industrial Area) may predict Pu activity monitored at GS08 (below Pond B5). In this case, GS10 and GS08 would be a monitoring location pair.

¹² Precipitation and snow melting conditions may also provide an acceptable model.

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - In order to provide a representative estimate of variability during FY98/FY99, it will be sufficient to monitor approximately one event per month at event monitoring stations (NSDs) and monitor a target of 20 samples taken over the full range of flow conditions, for each of the flow-paced stations (POEs and POCs) Monitoring at the POE and the NSD stations would represent the main drainage basins for which correlations are needed
 - Each of the stations must continuously monitor for turbidity due to the method (continuous probe) Monitoring for Pu and TSS at each of the event monitoring stations (SW022 and SW091) during every sampled event would provide adequate confidence that significant events are sampled and representative at those locations Monitoring for TSS at the flow-paced stations (GS10, SW093, SW027) should be performed only when Pu monitoring is performed and should provide at least 20 data pairs for FY98/FY99 The data set should include samples taken over the full range of flow conditions
- *Acceptable Decision Error Rates for Statistical Sampling Design*
 - Design of a sampling plan would require some knowledge of the variability, which is not yet available Samples taken during FY98/FY99 will provide this variability information so that a statistical sampling design may be implemented when possible
 - Acceptable decision error rate for the decision to accept the correlation between TSS and Pu as a design basis $r^2 \geq 0.8$ for three or more locations

Monitoring Requirements

The requirements shown in Table 2-4 are partially redundant with other decision rule monitoring requirements, but are specified here to retain the independence and separability of the monitoring requirements for each decision rule

Precipitation is currently measured in 5- and 15- minute intervals at nine locations around the Site The effective precipitation for any monitoring location drainage basin can be calculated from these data

2.3 Industrial Area Monitoring Objectives

This section includes the monitoring objectives for decisions regarding the Industrial Area¹³. Some of the monitoring performed to make these decisions is actually performed outside the Industrial Area. For example, to detect a new source of contamination within the Industrial Area, the Site actually monitors surface water just after it flows out of the Industrial Area.

This Industrial Area Monitoring section also addresses monitoring of incidental waters, the sanitary system, and performance monitoring. Immediately outside the buildings of the Industrial Area, the Site must often decide whether incidental waters (see Section 2.3.1) that accumulate in berms, utility pits, etc., can be discharged directly to the environment, or whether they must be treated. Discharges to the sanitary system are monitored as discussed in Section 2.3.2. Internal waste streams are discussed in Section 2.3.2.1. To maintain current information in the NPDES permit application, the Site must characterize all routine internal waste streams to establish what might reasonably occur in discharges from these processes. Additionally, the Site routinely determines whether nonroutine internal waste streams (Section 2.3.2.2) may be discharged from the Industrial Area to the WWTP. In addition, NPDES monitoring must be performed on the WWTP discharge to the ponds.

¹³ In the surface water monitoring objectives, the term "Industrial Area" is intended to include the 903 Pad. Runoff from the 903 Pad flows through monitoring stations SW022 and SW027.

2.3.1 Incidental Waters Monitoring

Problem Statement

Incidental water is precipitation, surface water, groundwater, utility water, process water, or wastewater collecting in one or more of the following areas

- Excavation sites, pits, or trenches,
- Secondary containments or berms,
- Valve vaults,
- Electrical vaults,
- Steam pits and other utility pits,
- Utility manholes,
- Other natural or manmade depressions that must be dewatered, or
- Discharges from a fire suppression system that has been breached within a radiological buffer area or a contamination area

For example, many precipitation events leave rainwater in some utility pits and secondary containments. Disposition of such waters depends on the contaminants present, if any, that may have been picked up from the surroundings or contaminant materials. Waters containing oil, radioactive constituents, and hazardous substances may require management (e.g., treatment, storage, or disposal) under appropriate regulations, rather than by direct discharge. This Incidental Waters Monitoring objective provides for the routine data-driven decisions on whether to allow discharge of these incidental waters into the environment. The Site must determine how to manage incidental waters (i.e., whether or not to discharge to the environment¹⁴).

This decision includes only incidental (not routine) accumulations of water (not waste). Discharges of water containing oil, radioactive constituents, and hazardous substances above the established control limits are prohibited. This monitoring objective does not include decisions regarding appropriate treatment of contaminated waters for which authorization to discharge to the environment is denied. This monitoring objective does

¹⁴ The environment, in these cases, includes storm drainages, surface waters, and the surface of the ground

not require laboratory analyses of snow melt, rain water, groundwater, or potable water, unless there is reasonable cause to suspect contamination

This program manages incidental water discharges of greater than 50 gallons. Waters that are denied discharge authorization under this decision rule may be considered for discharge to the WWTP under the internal waste stream decision rule elsewhere in this plan, or they may be managed using other treatment, storage, or disposal options.

Data Types and Frequency

The Site incidental waters program uses field screening observations and measurements, and chemical analyses for known or suspected constituents in order to determine the appropriateness of discharge to the environment. The field screening initial assessment is made on the basis of the screening criteria in Table 2-5.

**Table 2-5
Incidental Waters Screening Criteria**

Observation Parameter	Criterion
An estimate of volume	50 gallons
Process knowledge of the immediate vicinity	Professional judgement
Field pH using pH paper or similar indicator	pH 6 to 9
Appearance	Visible sheen or color
Field nitrate using probe, colorimetry, or similar indicator	10 mg/L
Field conductivity probe	700 $\mu\text{mho}/\text{cm}^2$

Notes

μmho = Micromhos L = Liter
 cm^2 = Square centimeter mg = Milligram

Additional testing is performed when known or suspected contaminants exist, including tests for gross alpha/beta, volatile organic compounds, and metals.

Boundaries

- Spatial* This decision is restricted to accumulations of water within the Industrial Area and within the Site Buffer Zone, where such waters may accumulate in containment structures and be contaminated to levels unacceptable for discharge.
- Temporal* Incidental waters are more common in rainy seasons, but may occur during any part of the year. Although the frequency of occurrence varies seasonally, there are no formal monitoring frequencies for the decision.

Decision Statement

- IF Incidental waters appear to be potable water or rain water accumulations that are collected in areas that have no potential for contamination (i.e., individual hazardous substance sites, material storage or handling areas, and high traffic areas) and initial screening tests or chemical analyses are negative—
- THEN Incidental waters may be discharged to the environment at the discretion of the Surface Water Program manager ¹⁵

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The Incidental Waters Program is well established, and there is low probability that accumulations of incidental waters would go unreported and unevaluated before being pumped and discharged to the environment
- Acceptable Decision Error Rates for Statistical Sampling Design
 - Recall that these accumulations of water in berms and utility pits are nearly always from rain, snow melt, groundwater, or potable water. If process knowledge, screening, and chemical analyses fail to indicate the presence of oil, or hazardous or radioactive substances, then the discharge is authorized. A single measurement or observation will be adequate, if performed at all. Therefore, a statistical sampling design is not applicable to this decision rule.

Monitoring Requirements

Monitoring of incidental waters will require field observation and screening, and additional chemical analyses of an estimated 15 incidental water accumulations per month during FY98/FY99. For each instance, screening is required, with additional chemical analyses

¹⁵ Incidental waters may also be discharged to the WWTP, with approval of the WWTP manager. However, the decision logic for these DQOs is that incidental waters become internal waste streams if they fail to qualify for discharge to the environment. Logically, there are three possible outcomes for the incidental water: the water may be discharged to the environment, subjected to the internal waste stream decision, or the responsible organization may elect to employ other treatment, storage, or disposal options. Therefore, the formal decision for incidental waters addresses only the discharge to the environment. The decision to discharge to the WWTP is handled as the internal waste stream decision elsewhere in this document, and the decision to manage under other regulations is out of scope for this document.

necessary when known or suspected contaminants exist For planning purposes, estimated monitoring targets for this monitoring objective are presented in Table 2-6

Table 2-6
Estimated Field Test Monitoring Targets (Number of Samples/Analyses)
for Incidental Waters

Parameter	Justification	Measurements per Year FY98/FY99
PH	NPDES permit and stream standards restrict pH of plant discharges Lab analysis of pH performed only if pH paper field test is inconclusive	120
Nitrate as N	NPDES permit and stream standards have restrictive nitrate limitations	120
Conductivity	Indicator parameter for metals NPDES permit and stream standards restrict metals	120
Gross alpha/beta	BMP to restrict radionuclides in SW discharges	90
VOCs	NPDES permit and stream standards restrict VOCs in SW discharges	30
Inorganic metals	NPDES permit and stream standards restrict metals in SW discharges	10

SW	=	Surface water

2.3.2 Sanitary System Monitoring

Sanitary collection system monitoring may provide the Site D&D project managers and WWTP operators information about collection system condition within the Industrial Area as specific areas contributing to the WWTP flow Current and prospective monitoring systems provide information about the relative contribution of the two main branches of the sanitary collection system and qualitative information about the content of flows through the headworks of the WWTP Sanitary system monitoring is conducted to

- Determine percent removals across the treatment plant and therefore be able to predict compliance or noncompliance with NPDES permit effluent limitations,

- Monitor explosive levels at the headworks for worker safety,
- Monitor for corrosive substances that may impact the treatment units,
- Determine if influent concentrations and loads are trending up or down, and
- Monitor within the collection system to establish pollutant loads attributable to specific industrial internal waste streams (e g , laundry water at the Site)

Five distinct monitoring requirements have been identified for sanitary system monitoring. Separate decision rules have been developed for each of these requirements. The first monitoring requirement is to characterize routine internal waste streams to meet NPDES permit requirements. This requirement is distinct from the nonroutine, for which separate requirements and decision rules have been developed. Finally, three requirements were identified for monitoring of the WWTP influent flows. These include collection system flow monitoring, WWTP protective monitoring, and WWTP radiological influent monitoring. The requirements and unique decision rules are described in the following subsections.

2.3.2.1 Internal Waste Stream Characterization to Meet Permit Requirements

Both of the next two sections deal with internal waste streams (IWS) but have very different decision rules and monitoring requirements. These IWS Monitoring objectives address two of the most conceptually complex surface water decisions to be made. These are decisions regarding disposition of contaminated waste streams produced on Site. Some can be discharged to the sanitary system, some must be treated under the Resource Conservation and Recovery Act (RCRA), some require treatment for radionuclides under DOE Orders, and some require management by still other regulations. These related issues, neither of which is monitoring required by the RFCA, are introduced below.

- The first main NPDES issue is that the Site must maintain strict compliance with NPDES permit conditions. This compliance requirement drives two distinct monitoring activities:
 - The Site must monitor permitted discharges as specified in the permit and report as specified in the permit. This issue of NPDES compliance monitoring is covered below.
 - The Site must manage discharges to the WWTP for two reasons that are combined operationally under the “authorization to discharge” process.

- 1 The Site must ensure that the operational capabilities of the WWTP are not exceeded, resulting in a permit violation for the WWTP effluent This activity is covered in Section 2 3 2 2
 - 2 The Site must ensure that waste streams discharged to the WWTP are compliant with the NPDES permit, DOE Orders, and other regulations This activity is also covered in Section 2 3 2 2
- The second main NPDES issue is that of working with regulators toward well-informed decisions regarding permit conditions for the next NPDES permit or permit modification (This is an ongoing process, so there is always a “next” permit or permit modification) The Site provides input to the decision process through preparation and maintenance of the NPDES permit application This second monitoring issue is covered in this section

The quantity and complexity of this activity will increase during D&D and implementation of the 10-Year Plan As the Site population decreases, the quantity of aqueous waste streams may decrease But as the mission changes, process streams will undergo significant changes that must be reflected in the permit application New challenging waste streams will arise more frequently as buildings are deactivated and drained of their fluid contents and as other facilities modify their operations accordingly

Problem Statement

Determining appropriate permit conditions is, in part, a data-driven process The Site provides the data, and the regulators make the decisions Data for these decisions are provided in the NPDES permit application Data used in the permit application include detailed information about process streams emanating from buildings in the Industrial Area and discharged to the collection system The nature of all Site processes and a detailed characterization of certain¹⁶ discharges must be included in the permit application These characterizations must include flow rates, constituents, and concentrations Routine discharges are most likely to be monitored and may be incorporated in the NPDES permit

Problem Scope

The permit application has been supplemented with information about most internal waste streams and incidental waters that discharge to surface water Sanitary discharges and process waste streams from all Site buildings, and discharges from Building 374, the

¹⁶ The Clean Water Act (CWA) regulations require specific information about waste streams that arise from categorical processes identified in 40 CFR 400-500

WWTP, and the terminal ponds are potential monitoring targets included within the scope of this section

The main objective covered in this section is that the Site must keep the permit application current. This will require that the Site characterize new waste streams for disclosure in the permit application. The following are excluded from the scope of this section:

- Process or sanitary discharges of any quantity (internal waste streams) are subject to evaluation under Section 2.3.2.2
- Incidental waters (which do not contain oil, or hazardous or radioactive substances) are covered in Section 2.3.1 of this document. Stormwater runoff monitoring is excluded from this section.

Data Types and Frequency

- The following items are included in the permit application, as needed:
 - Complete NPDES application,
 - Update notifications that have been presented to the permitting agency,
 - Current drawings for each facility,
 - Descriptions of discharges from the facility to waters of the United States, and
 - Current available characterization for each discharge

Boundaries

Spatial The data collected for this monitoring objective is limited to the Industrial Area. All facilities and all storm water drainages from the Industrial Area are included.

Temporal This section has no temporal boundaries, it deals only with present and future discharges. The permit application requires resubmission every five years.

The actual data-driven decision is made by the regulator. That is the decision whether to establish a permit condition, limitation, or requirement.

RFETS Integrated Monitoring Plan

in response to a specific contaminant concentration in a specific discharge stream described in the permit application

Decision Statement

IF	Any facility on Site discharges wastes to surface water directly or indirectly through a treatment facility—
THEN	The discharge must be characterized and must be reflected in the permit application

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - Site processes for review, notification, and approval of facility modifications are not fully implemented in some cases. Often, facility inspections are needed to provide complete identification and full disclosure of discharges. A planned approach to thoroughly inspect facilities and processes should be used to provide completeness for the permit application.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - Regulatory emphasis is on full disclosure rather than on accuracy. A rigorous statistical treatment is inappropriate for this decision because typically only one analysis will be performed. Therefore, sampling variability will not be evaluated and will not drive additional sampling to achieve some desired confidence level. Analytical results are required to be representative of typical conditions in discharged waste streams, but failure to report a discharge carries a greater risk than flawed characterization. Therefore, completeness is more important than the rigor of a statistically designed sampling protocol, except in those cases where the Site elects to negotiate a specific issue and requires project-specific monitoring data to negotiate that issue. Such monitoring is not addressed in this plan.

Monitoring Requirements

For planning purposes, it is estimated that three new waste streams will require characterization each year during FY98/FY99 in order to maintain the NPDES permit application.

2.3 2.2 Monitoring Discharges to the WWTP

This section addresses the monitoring for granting authorization to discharge a waste stream to the WWTP. The Site must make frequent decisions regarding disposition of waste streams. Nonroutine incidental process discharges must be evaluated prior to discharge into the WWTP. NPDES, RCRA, and other regulations prohibit discharge of some hazardous, toxic, radioactive, and otherwise regulated materials to the WWTP.

This section covers nonroutine process or sanitary discharges. Incidental waters (which do not contain oil, or hazardous or radioactive substances) are covered in Section 2.3.1 of this document. Stormwater runoff monitoring is excluded from this section.

If waste streams may not be discharged to the WWTP, then they may need to be evaluated for treatment, storage, or disposal under appropriate regulations such as RCRA, CERCLA, or DOE Orders prior to discharge. However, monitoring for treatment decisions is outside the scope of this environmental monitoring plan.

There are five sets of criteria against which monitoring may be required to verify compliance, depending on process knowledge:

- NPDES regulations prohibit certain hazardous substances from being discharged to surface water. Table A-24 (see Appendix A to this section) shows a list of NPDES hazardous substances that must be considered (but not necessarily analyzed) during the characterization of each internal waste stream. Sampling required to characterize each discharge is subject to process knowledge available and is limited to those analytes reasonably expected to be present.
- WWTP operational capabilities limit the loading of many substances and the values of some physical parameters, such as pH, in the WWTP influent stream. Table A-25 (see Appendix A to this section) specifies these limitations.
- RCRA hazardous wastes are also prohibited from being discharged to surface waters, and discharge to the WWTP is regulated. RCRA regulations for listed, characteristic, and derived hazardous wastes are included in this document by reference only.
- Oil in WWTP influent streams is limited to 100 milligrams (mg)/L unless a greater loading is specifically authorized by the WWTP manager.
- Radionuclides discharged to the WWTP are limited to loadings that will not result in exceedance of Segment 4 stream standards under RFCA. As low as reasonably achievable (ALARA) also applies to discharges of radionuclides.

Data Types and Frequency

Process knowledge is the most valuable indicator. Process knowledge might include the source of the waste stream, current location, and historic precedent. Screening inputs are shown in Table 2-7. Additional chemical analyses are performed when process knowledge and screening results are insufficient to adequately characterize a waste stream.

Table 2-8
Requests (Number of Samples/Analyses)
for Authorization to Discharge

Requests	Total	Approved	Denied
Number of Requests for FY97	52	48	4
Number of Requests for FY98 (through May)	34	32	2

Notes

FY = Fiscal year

Numbers shown are examples for planning purposes in future years

All facilities within the Industrial Area are included under this monitoring objective. This monitoring objective has no temporal boundaries, except that it deals only with present and future discharges. All liquids for which a facility requests authorization to discharge to the WWTP are included under this objective. Examples include chemical solutions, condensate, foundation drainage, some incidental waters that are not acceptable for discharge to the environment, and new process discharges.

Decision Statement

The ideal decision rule is stated below

IF A waste stream for which a facility has requested authorization to discharge to the WWTP fails to qualify under any applicable regulatory criterion—

THEN Do not authorize discharge to the WWTP

This ideal rule requires the decision maker to be virtually omniscient. Some finite, practical, and protective monitoring must be implemented to approach the ideal. The practical decision rules used to implement this monitoring objective are presented below

IF Process knowledge and the standard screening protocol shown in Table 2-7 offer no reasonable cause to suspect prohibited contaminants in a waste stream for which authorization to discharge has been requested—

THEN The Site will grant authorization to discharge to the WWTP, subject to approval of the WWTP manager

IF Screening results¹⁷ or process knowledge indicate that contaminants would prohibit the discharge under any applicable regulation—

THEN The Site will either

- Deny the request to discharge, or
- Perform more specific analyses and evaluate the estimated contaminant load to the WWTP and estimated contaminant concentrations discharged to the main stream channels of waters of the state after passing through the WWTP or ponds

IF More specific or more sensitive analyses indicate that the waste stream would not cause a violation of applicable regulations—

THEN The Site will authorize discharge to the WWTP with the approval of the WWTP manager

¹⁷ Screening results may be single values or averaged values at the discretion of the surface water manager or WWTP manager

The responsible organization may elect to perform additional analyses at their expense to resolve concerns raised by process knowledge or screening tests

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative and Acceptable Decision Error Rates for Statistical Sampling Design
 - A single sample will typically be appropriate, and a statistical sampling design will not be needed

Monitoring Requirements

The Surface Water IMP Team estimates that there will be approximately 40 requests each year for authorization to discharge during FY98/FY99. Each will be screened as specified in Table 2-7. This is due to grouping several similar waste streams (e.g., barrels) into single requests for administrative efficiency.

2.3.2.3 WWTP Collection System Protective Monitoring

At this time, collection system protective monitoring is minimal and consists of real-time monitoring for pH, conductivity, and Lower Explosive Limit (LEL) at two locations, in the equalization basins and at the headworks to the plant. Some manual pH readings are also taken by plant personnel at the headworks. As D&D proceeds and buildings with drains to the WWTP are impacted, the need to expand the collection system monitoring will be evaluated.

The pH and conductivity monitoring are indicators for corrosivity and spills. LEL readings are for protecting worker safety and have a separate decision rule.

Data Types and Frequencies

The following indicators should be considered: pH, conductivity, LEL, and monitoring for radionuclides.

Boundaries

- | | |
|-----------------|---|
| <i>Spatial</i> | All collection system lines influent to the WWTP up to but not including lines inside the buildings inside the Industrial Area. |
| <i>Temporal</i> | This is real-time operational monitoring. |

Decision Statement

Proposed decision rules to be developed for FY98 are presented below

- | | |
|------|--|
| IF | pH or conductivity monitoring shows uncharacteristic changes over past results— |
| THEN | The chief operator will be notified and will determine whether the influent should be rerouted to the flow equalization basin not currently in use while the problem is investigated |
| IF | The LEL is exceeded (see Table A-25)— |
| THEN | Emergency procedures will be activated |

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - To be determined
- Acceptable Decision Error Rates for Statistical Sampling Design
 - To be determined

Monitoring Requirements

To be determined

2.3.2.4 WWTP Collection System Flow Monitoring

Flow information for the Site's sanitary collection system is currently limited to influent records for the WWTP. The initial scope of collection system monitoring is intended to provide Site collection system flow information by installing continuous recording flow monitoring equipment at (Building 990) on the two main collection system lines. The flow record will be used to establish annual baseline conditions for the flows from the protected area (PA) and non-PA areas. Changes from the established baseline flow may be attributable to normal collection system conditions such as infiltration and inflow, or abnormal conditions, such as increased flows from areas undergoing D&D.

Problem Statement

The sanitary collection system consists of two components, one serving the Protected Area and one serving all areas outside of the Protected Area (PA and non-PA, respectively). Flows from the two areas remain segregated until they enter the equalization basins located at B990. Influent to the WWTP (B995) is monitored for pH, conductivity, and LEL on a continuous basis. These parameters are also monitored at B990 on both the PA and non-PA systems. None of these locations has a continuously recording flow monitoring device.

Data Types and Frequencies

Installation of the described equipment will facilitate the collection of flow rates on the PA and non-PA collection systems. These inputs can be combined with currently recorded pH, conductivity, LEL levels, and precipitation and other existing continuous monitoring programs.

Boundaries

Spatial The areas described in the problem statement and scope are all areas at RFETS served by the existing sanitary collection system.

Decision Statement

IF A baseline for flow does not exist—

THEN Develop a baseline and correlate its relationship with ground water levels and precipitation.

After developing a collection system flow baseline

IF Flow in the PA or non-PA collection lines deviate from the baseline influent flows—

THEN Identify the source of abnormal flows and evaluate the impact on the sanitary collection system.

Monitoring Requirements

Continuous flow monitoring of the sanitary collection system in the main transmission lines from the PA and non-PA areas into B990.

2 3.2.5 WWTP Radiological Monitoring

This section also includes the monitoring of radiological parameters at the influent to the WWTP for the purpose of tracking pollutant loads coming through the WWTP collection system. The assumption is that these radiologic loads to the WWTP should be decreasing, since the Site has systematically tried to eliminate any possible connections between wastestreams containing radionuclides and the collection system.

Problem Statement

With the onset of D&D activities and remedial actions, the possibility of introducing contamination into the WWTP exists. Monitoring is one way to track whether there is an impact by an unknown source to the WWTP as a result of clean up activities.

Data Types and Frequencies

Influent WWTP monitoring will include the suite of radiological parameters: isotopic Pu, Am, uranium (U), tritium, plus alpha and beta activity. Influent flow is also a required input in order to determine the loading into the treatment plant. Effluent WWTP monitoring includes the suite of radiological parameters: isotopic Pu, Am, U, tritium, plus alpha and beta activity.

Boundaries

<i>Spatial</i>	All collection system lines influent to the WWTP and WWTP effluent
<i>Temporal</i>	Present and future influent and effluent to the WWTP

Decision Statement

IF	A baseline for influent radiological levels does not exist—
THEN	Establish a baseline with initial loading data for WWTP radiological influent monitoring

After developing a influent radiological baseline

IF	Influent loading for any radiological constituents show a significant increase over the established baseline—
THEN	An evaluation will be conducted to determine potential cause

The WWTP radiological effluent monitoring data will be compared with influent data to evaluate WWTP removal efficiency

Monitoring Requirements

For the 1998 IMP, the Site will collect a 24-hour composite sample at the headworks to the WWTP, at a time representative of full operation of the complex (not on weekends). The volume of flow associated with the 24-hour composite needs to be provided by the Site and made available to CDPHE. CDPHE will pick up the composite sample from the Site and will perform the analyses and calculate the loadings. For 1998, the sampling frequency will be once per month.

The Site collects an 8-hour composite sample of WWTP effluent once a month. The sample is analyzed for isotopic Pu, Am, U, and tritium. Alpha and beta screens are performed twice monthly.

Sampling protocol and data quality objectives for WWTP monitoring are specified in the related sampling and analysis plan.

2.3.3 Performance Monitoring

Problem Statement

This section addresses monitoring the performance of specific actions¹⁸ on Site for the release of contaminants to the environment. Project-specific performance monitoring may be detailed in a project plan through the review and approval process when the project poses a concern for a specific contaminant release, especially for a contaminant that may not be adequately monitored by other monitoring objectives downstream. Each performance monitoring location will target the contaminants of greatest concern for the specific action being monitored. For example, performance monitoring for specific analytes may be needed for

- **D&D Actions** The review and approval process for a D&D action may identify the need for performance monitoring specific to that action.
- **Remedial Actions** There are monitoring requirements associated with specific Operable Unit (OU) activities. For example, the existing consolidated treatment plant for OU1 and OU2 has a surface water discharge. Performance monitoring specific to this discharge is specified in the work plans.

¹⁸ This is project specific versus the global monitoring (NSD and POE) of the Industrial Area discussed in Sections 2.4.1 and 2.4.2.

- **Transition Actions** For example, DOE, RFFO has proposed changes in the operation of the ITS. Specific performance monitoring may be needed in light of this change if other monitoring in this IMP fails to provide adequate assurance of protecting the environment and public health.
- **Best Management Practices (BMPs) for the Control of Plutonium Transport in Surface Water Runoff** For example, when a BMP (barrier, trap, filter, or other watershed improvement) is installed to control a potential source of Pu-contaminated runoff, the Site would like to determine the effectiveness of the BMP so that resources may be allocated where they are most effective.

Monitoring of activities within the Industrial Area is achieved, in general, through the NSD and POE monitoring (see Sections 2.4.1 and 2.4.2 for details).

Project-specific performance monitoring stations must be portable to monitor specific high-risk Site activities, such as D&D activities for a particular building. These mobile, temporary stations will be placed upstream from the routine monitoring stations, closer to specific Site activities to monitor a sub-basin for releases of contaminants specific to the activity in the sub-basin.

Boundaries

<i>Spatial</i>	Performance monitoring can occur anywhere within the Site surface water drainage areas (especially within the Industrial Area), downstream from a BMP, remediation, or high-risk activity.
<i>Temporal</i>	Generally, monitoring is initiated with enough time prior to project activities such that 10 - 15 samples over varying flow rates can be collected (preferably 18 months prior to project initiation ¹⁹). Results from these samples are used to establish a baseline for the sub-basin. Monitoring continues during the activity attempting to collect one sample per month. After project completion, monitoring continues long enough to determine any beneficial impacts to surface-water quality.

Data Types and Frequency

The types of data to be collected must be specified in the project plan. Analyte suites are generally determined by the constituents of concern associated with a specific activity or location. Generally, automated samples are flow-paced composites of 15 grabs taken on

¹⁹ Due to the dynamic nature of Site Cleanup, initiation of performance monitoring 18 months prior to an activity is rarely achieved. However, additional samples are often collected at an increased rate to establish baseline prior to initiation of project activities.

the rising limb of a runoff event. However, protocols may be modified depending on the specific conditions for a monitoring location or drainage basin. For example, a location with substantial groundwater seepage or a periodic footing drain discharge may warrant monitoring of those flows. Regardless, the sampling protocols are designed to accurately characterize existing flows and confidently monitor for changes during the project activities.

With the administrative transfer of OU2 monitoring (see Table 2-9) to the IMP to facilitate closeout of OU2 IM/IRA activities, quarterly grab samples are collected and analyzed as specified in the OU2 closure document. Reporting for these locations will be included in the quarterly report and no longer be reported in the Consolidated Water Treatment Facility report.

Decision Statement

Decision rules must be specified for individual projects. A project-specific indicator might be a single monitoring result, a 30-day average for a specific analyte, or an indicator for the analyte of concern. Example decision rules are shown below.

IF	The project-specific indicator is greater than the 95% upper tolerance level (UTL) of baseline—
THEN	The Site will evaluate the specific activity to improve performance.
IF	The project-specific indicator is less than the 95% lower tolerance level (LTL)—
THEN	The Site will conclude that the project has reduced environmental releases of the specific contaminant.

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The specific project plan must specify an adequate monitoring method.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - The specific project plan must specify the decision criteria. Examples are shown in the decision rule section, above.

Monitoring Requirements

Monitoring details will be specific to the project. The projected performance monitoring to take place in FY98 is given in Table 2-9. Analyte suites and sample collection protocols are project-specific and are contained in the individual project plans for automated locations. This same information can be found in the Surface Water (SW) Monitoring Technical Design Document (RMRS, 1996) which can be obtained from RMRS Water Management and Treatment (WM&T) personnel. The performance monitoring for FY99 will depend on Site closure activities and schedules.

**Table 2-9
Projected FY98 Performance Monitoring Locations**

Location Code	Location Description	Project	Supporting Documentation
GS27	Small ditch NW of B884	D&D of B889, Watershed Improvements evaluation	SW Monitoring Technical Design Document
GS32	Corrugated metal pipe (1.5 ft) north of Solar Ponds in PA draining B779 area	D&D of B779	SW Monitoring Technical Design Document
GS37	Central Ave Ditch north of B443	D&D of B123	SW Monitoring Technical Design Document
GS39	Corrugated metal pipe (1.0 ft) north of 904 Pad draining 903/904 Pads and Contractor Yard areas	ER projects for 903 Pad, also serves as Source Location monitoring station for GS10 Source Evaluation	SW Monitoring Technical Design Document
SW061 ²⁰	S Walnut Creek upstream of B995	OU2 Closure	Final Surface Water Interim Measures/Interim Remedial Action Plan/ Environmental Assessment and Decision Document, S Walnut Creek Basin
SW132	S Walnut Creek, outfall of culvert draining 700 and 900 Areas, south of B995	OU2 Closure	Final Surface Water Interim Measures/Interim Remedial Action Plan/ Environmental Assessment and Decision Document, S Walnut Creek Basin

²⁰ The inclusion of SW061 and SW132 monitoring in the IMP completes the OU2 IM/IRA administrative transfer of former OU2 monitoring.

2.3.4 National Pollutant Discharge Elimination System Permit Monitoring

The NPDES permit program controls the release of pollutants into the waters of the United States and requires routine monitoring of point source discharges and reporting of results. The Site's first NPDES permit was issued by EPA in 1974. The current permit was reissued by EPA in 1984, expired in 1989, and has been administratively extended to date. A draft permit has completed the public comment process and is awaiting issuance by EPA. All monitoring for NPDES compliance is prescriptively required by EPA and is not covered by the IMP process or detailed in this document. Please refer to the current permit for specific monitoring requirements.

Current Permit

The current permit for the Site identifies six monitoring points for control of discharges. These locations include the effluent of the WWTP, two interior ponds, and three terminal ponds capable of discharging water off Site. The NPDES permit terms were modified by the Federal Facility Compliance Agreement (FFCA) signed on March 25, 1991 (DOE, 1991). Modifications included the elimination of inactive discharge points and inclusion of new monitoring parameters at other discharge locations.

Draft Permit

The draft permit for the Site is expected to address only two permitted discharge points, the WWTP effluent and Building 374 product water effluent. The other previously permitted discharge locations will be regulated under CERCLA via the RFCA. Additional expanded scope includes plans and procedures for operations of influent/effluent storage tanks, influent monitoring at WWTP, internal wastestream monitoring, stormwater monitoring, stormwater pollution prevention plan, and WWTP influent real-time radiological monitoring feasibility study.

2.4 Monitoring Objectives for Industrial Area Discharges To Ponds

This section addresses monitoring of surface water before it arrives in the terminal ponds (i.e., surface waters running off of the Industrial Area to Segment 5 waters upstream of the terminal ponds). These discharges are the major transport pathways available for contaminants leaving the Industrial Area. Ongoing activities and remediation tasks at the Site could create new contaminant source areas within and around the Industrial Area and could thus degrade downstream surface-water quality. For example, a D&D or remediation project could result in the release of contaminants to soils near the facility, which could be transported via runoff into Site drainages, and possibly off Site.

The Site must monitor runoff to detect significant spills or leaks from ongoing activities such as remediation, D&D, construction, and continuing operations. Merely monitoring the terminal

pond discharges is not adequate to protect water quality above the terminal ponds (in compliance with RFCA requirements), or to detect acute contaminant runoff from significant new sources within the Industrial Area

2 4.1 New Source Detection Monitoring

The NSD Monitoring objective provides comprehensive coverage of the entire Industrial Area but is not specifically focused on individual actions within the Industrial Area. Performance monitoring of specific activities within the Industrial Area (or elsewhere) may be carried out under the Performance Monitoring objective. This NSD objective monitors the performance of all remedial activities within the Industrial Area with respect to their impact on surface waters. However, it does not necessarily identify and locate a specific source within the Industrial Area.²¹ This monitoring objective provides for monitoring of all main drainages from the Industrial Area into the three main channels of Stream Segment 5.²²

This NSD monitoring is one of many possible spill response actions, but spill response is not the primary focus of the NSD Monitoring objective. Sampling and analysis of spills is addressed in other Site planning documents, such as the *Spill Prevention, Control, and Countermeasures/Best Management Practice Plan* (SPCC/BMP) (EG&G, 1992a).

Data Types and Frequency

This decision requires contaminant concentration data from surface water samples taken at permanent monitoring locations located on the five main surface water pathways to the Site detention ponds. Analyses are performed for each of the contaminants and parameters listed below in order to establish a baseline. After a baseline has been established, evaluations will be performed as required by the decision rules. The basis for selecting these contaminants of concern and indicator parameters is described below.

- Isotopic Pu, U, and Am are primary contaminants of concern
- Turbidity, pH, nitrate (NO₃), and conductivity are measurements performed continuously because they are inexpensive per measurement and can be used as real-time indicators to provide or negate reasonable cause to analyze for other specific contaminants
- Turbidity may indicate increased contaminant loads in general and increased Pu specifically (Pu in surface water is generally bound to particulates)

²¹ Location of a specific source would be performed under the Source Location Monitoring objective in Section 2 2 2

²² The Site also desires early detection of smaller releases within the Industrial Area, by monitoring closer to the anticipated sources during D&D activities. This will be achieved through the Performance Monitoring objective (see Section 2 3 3)

- pH can be used to detect an acid or caustic spill
- Nitrate may be useful in detection of chemical spills that include plutonium nitrate
- Conductivity can be used to corroborate a pH reading and to detect salt solution spills or metal spills such as chromium (Cr), beryllium (Be), silver (Ag), or cadmium (Cd)
- Precipitation can be used to determine whether a flow event is rain/snow runoff or a spill. Precipitation data is collected at nine locations across the Site. Effective precipitation for a given monitoring location drainage can be calculated
- Water flow rate is needed to identify an event, trigger an automatic sampler, control the flow-paced sampling, and evaluate the magnitude of the spill or contaminant source (mass loading)
- Small changes to base flow not attributable to rain or snowmelt or an unusual runoff hydrograph shape may indicate a spill

This monitoring objective is limited to information collected at the Industrial Area boundary, as represented by surface-water monitoring stations SW022, SW091, SW093, SW027, and GS10²³ (see Figure 2-4). This monitoring focuses on runoff into the three main drainage areas leaving the Industrial Area: North Walnut Creek, South Walnut Creek, and the South Interceptor Ditch/Pond C2 drainage (see Figure 2-3 and Figure 2-4). Normally, SW022 waters are subsequently monitored at GS10, so there is some redundancy in this set of monitoring stations. SW022 has been included at the request of the EPA to provide increased sensitivity for its drainage area. SW022 would also be used to determine the location of any new source detected at GS10.

For SW022 and SW091, sampling is event-specific, focused on the time period during which the first flush conditions prevail, specifically, the time period during the rising limb of a direct runoff hydrograph after any storm event. Automatic samplers are triggered when direct runoff is detected at the location [for example, >0.1 cubic feet per second (cfs), location specific]²⁴. The sample is analyzed when the runoff volume [for example,

²³ Subdrainage monitoring stations within the Industrial Area are used for performance monitoring and source location but are excluded from the planned monitoring for this NSD decision rule.

²⁴ Note that specific boundary conditions are not procedural, legal, quality assurance (QA), or policy requirements. They serve only to clarify the objective so that a decision rule can be articulated. The flow rate and volume given in the text are only examples and may never actually be used in the field. These parameters vary greatly, depending on the season and the character of runoff events common during that season (e.g., snow melt or thunder shower). The parameters are selected such that representative samples can be collected on the rising limb for varying flow rates, runoff conditions, and seasons.

>25,000 gallons (gal)] is sufficient such that a flow-paced composite sample (in a 15-L carboy) can be collected that represents the first flush (presumed water-quality worst case). Seasonal adjustments are applied to define the conditions that represent first flush and direct runoff. Professional judgement will be used to select the most representative sample for each month from each station for analysis, when a sample is available for that month at that station. Samples are selected to provide analytical results for rising limbs with varying flow rates and runoff characteristics. This monitoring pushes the limits of the sampling equipment, and collection of one representative sample a month is an appropriate goal.

For SW093, GS10, and SW027, the information used in the NSD objective will be the same data as collected from the continuous flow-paced sampling used for monitoring Segment 5 action levels (see Section 2.4.2). These POE stations have base flow, whereas the other two stations do not.

Only surface-water runoff from the Industrial Area is included, (i.e., base flow, stormwater runoff flow, and spills to surface water). Spills are only included in this NSD monitoring as a secondary monitoring objective if an increase in flow rate is detected and cannot be attributed to precipitation, snow melt, or other previously monitored discharge. However, other management controls (e.g., SPCC/BMP) address monitoring of spills as a primary objective. These locations also provide confirmation that containment measures for spills or accidental discharges have been effective through monitoring of the real-time indicator parameters and subsequent analyses of collected samples.

Indicator monitoring will be performed for the parameters specified at the top of each column of Table 2-10. The first three columns are AoIs monitored directly through sample analytical measurements. Although these three columns and rows have a different relationship than the others, they have been included so that all monitored parameters are shown on the same table. The remaining columns are indicator parameters that are monitored with inexpensive real-time probes in lieu of analyzing for the AoIs identified at the left of each row. If a significant increase is detected in any one of these indicator parameters, then there is reasonable cause to suspect the presence of the AoI identified at the left end of the row in which an "X" appears. For example, if the nitrate probe detects a high nitrate concentration, then the Site would have reasonable cause to suspect the presence of plutonium nitrate, extreme pH, cadmium nitrate, and, of course, high nitrate, all of which are AoIs for Segment 5. If there were reasonable cause to suspect the presence of these AoIs, then the Site could perform additional analytical procedures specific for the AoI.

Decision Statement

Screening for reasonable cause to suspect a new source

IF The mean concentration of any of the screening indicator variables in Table 2-10 exceeds the 95% UTL of baseline for that variable—

THEN The Site will evaluate the need for further action under RFCA ALF, such as source evaluation and control. Evaluations will address persistence, trends, and risk of action level exceedances at POEs

Table 2-10
Screening for New Source Detection AoIs vs. Indicator Parameters

AoIs	Routinely Monitored Parameters							
	Monitored AoIs			Indicator Parameters for AoIs				
	Pu	U	Am	Turbidity	pH	Conductivity	NO ₃	Flow Rate and Precipitation
Plutonium	X			X			X	X
Uranium		X						X
Americium			X	X				X
Turbidity				X				X
pH					X		X	X
Conductivity						X		X
Nitrate						X	X	X
Chromium					X	X	X	X
Beryllium						X		X
Silver						X		X
Cadmium						X	X	X

Notes

Am = Americium
 AoIs = Analytes of interest
 NO₃ = Nitrate
 Pu = Plutonium
 U = Uranium

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The Site desires detection through sampling of runoff events within a month of a significant new contaminant release ²⁵ This is achieved through sampling all major drainages from the Industrial Area during high flow and analyzing approximately one sample per station per month The Site must monitor runoff events at four locations (SW093, SW091, GS10, and SW027) to provide an acceptable level of confidence that significant events will be observed Monitoring at SW022 is not required for the desired confidence
- Acceptable Decision Error Rates for Statistical Sampling Design
 - Baseline is defined by an average value for the parameter of interest over all monitored precipitation events for a single baseline year, at the discretion of the DOE, RFFO A single measured value is accepted as representing a contaminant of interest If a single measured value exceeds the 95% UTL of baseline, that will provide adequate confidence of new source detection and invoke the action(s) specified by the decision rule

Monitoring Requirements

Table 2-11 presents detailed monitoring requirements for this decision rule Analytical and real-time, water-quality probe indicator monitored parameters are in Table 2-10

²⁵ Runoff events may be more than a month apart The intent here is to detect a release to the environment from within the Industrial Area that is being flushed out of the Industrial Area by a runoff event within a few weeks

Table 2-11
Monitoring Requirements (Number of Samples) for New Source Detection

Monitoring Station	SW093	SW091	GS10	SW027	SW022
Sample Analyses					
Total Pu-239/240	12/year ^a	12/year	12/year ^a	12/year ^a	12/year
Total Am-241	12/year ^a	12/year	12/year ^a	12/year ^a	12/year
Total U Isotopes	12/year ^a	12/year	12/year ^a	12/year ^a	12/year
Real-Time, Water-Quality Probe Indicator Parameters					
pH	15-min	15-min	15-min	15-min	15-min
Specific Conductivity	15-min	15-min	15-min	15-min	15-min
Turbidity	15-min	15-min	15-min	15-min	15-min
Nitrate	15-min	15-min	15-min	15-min	15-min
Flow	15-min	15-min	15-min	15-min	15-min
Precipitation	Site-wide locations				

Notes

^a Only SW091 and SW022 will be monitored for the rising limb of the hydrograph, as originally specified for this decision rule. Stations SW093, SW027, and GS10 are the Segment 5 action level (POE) monitoring stations. At these Segment 5 stations, NSD will be performed by statistically testing the flow-paced sample results. The same test criterion will be used, except that flow-paced samples will be tested against flow-paced variability. These locations will collect more than the target 12 samples for the NSD objective. All results collected at these locations under the POE objective will be used in the NSD objective.

Am = Americium Pu = Plutonium
 U = Uranium min = minute

2.4.2 Stream Segment 5/Point of Evaluation Monitoring

This monitoring objective deals with POE monitoring of Segment 5 for adherence with RFCA action levels. RFCA provides specific criteria for virtually every possible contaminant for the main stream channels of Segment 5. In Table A-26 (presented at the end of this section in Appendix A), the DQO team identified a subset of those contaminants that are of sufficient interest to warrant monitoring. Figure 2-3 illustrates the stream segments, and Figure 2-4 shows the monitoring points used for various decisions.

Responses to exceedances at POEs are different than the responses associated with contaminated runoff before it reaches Segment 5 or after it enters Segment 4. Industrial Area monitoring upgradient of Segment 5 is designed to detect new contaminant sources within the Industrial Area. Downstream, Segment 4 is monitored at POCs to determine compliance with RFCA standards. This subsection of the document deals with POE monitoring of Segment 5 for compliance with RFCA action levels.

Historical data indicate that several regulated contaminants may exceed their RFCA action level criteria at the designated POEs. Such exceedances will require source evaluation and the development of a mitigation plan. The initial response to these exceedances might be to invoke the source location decision rule, perform special monitoring tailored to the specific source evaluation, and take action upstream of Segment 5 to protect Segment 5 from contaminant sources that caused such exceedances.

Data Types and Frequency

The necessary decision inputs are those analytes specified as the Segment 5 AoIs per Table A-26 (see Appendix A to this section), as sampled at the POEs for Stream Segment 5. Segment 5 includes the terminal ponds (A4 and B5), and the main stream channels of North and South Walnut Creek, Pond C2, and the SID. Monitoring will be performed for Stream Segment 5 only as represented by POEs SW093, GS10 and SW027 (see Figure 2-4).

Sampling for AoIs at POEs is performed by collecting continuous flow-paced composite samples. Indicator parameters are measured using real-time, water-quality probes. These AoIs and indicator parameters are evaluated using 30-day or 1-day moving averages, as specified in RFCA²⁶ and implemented by the ALF or DQO working groups involving consensus of all parties to RFCA. Pu, Am, U, Be, Cr, dissolved Ag, and dissolved Cd are evaluated using volume-weighted 30-day moving averages at these POEs.²⁷ Indicator parameters pH and nitrate are evaluated as one-day arithmetic averages (averaging of pH takes into consideration the logarithmic characteristics of pH measurement).

Moving averages are to be calculated for the preceding period, verified by additional analyses at the discretion of the monitoring organization, and formally reported to the DOE, RFFO within 30 days of gaining knowledge that an exceedance may have occurred (i.e., within 30 days of receiving a high analytical result). This 30-day period allows time for verification analyses after the monitoring organization gains knowledge that an exceedance may have occurred before formal notification to DOE, RFFO of an actual exceedance is required. RFCA requires that DOE, RFFO inform regulators within 15 days of DOE, RFFO gaining knowledge (not just a suspicion) that an exceedance (verified) has

²⁶ Moving averages are to be calculated on whatever data are available, which may range from N=0 to more nearly ideal sample sizes computed on the basis of variability and confidence levels, unaffected by budgetary constraints. Where N=0, the average is not available. Where N=1, the average is the value for that single sample.

²⁷ The 30-day average for a particular day is calculated as a volume-weighted average of a "window" of time containing the previous 30-days which had flow. Each day has its own discharge volume (measured at the location with a flow meter) and activity (from the sample carboy in place at the end of that day). Therefore, there are 365 (366 in a leap year) 30-day moving averages for a location which flows all year. At locations that monitor pond discharges or have intermittent flows, 30-day averages are reported as averages of the previous 30 days of greater than zero flow. For days where no activity is available, either due to failed laboratory analysis or NSQ for analysis, no 30-day average is reported.

(actually) occurred During this 45-day period between first suspicion and formal notification to regulators, the DOE, RFFO may initiate discretionary mitigating action The delay interval will prevent undue public alarm when the initial high result is not confirmed by subsequent monitoring Informal communications between the parties are intended during the delay interval

Decision Statement

IF The appropriate summary statistic²⁸ for any AoI²⁹ in the main stream channels of Stream Segment 5, as monitored at the designated POEs,³⁰ exceeds the appropriate RFCA action level—

THEN The Site must notify EPA and CDPHE, evaluate for source location, and implement mitigating action³¹ if appropriate³²

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The flow-paced monitoring method ensures that significant events will be sampled This method involves taking a fixed volume [e g , 200 milliliters (ml) or 1 L] into the composite sample carboy (e g , 15 - 22 L) as each Nth volume of flow [e g , 500 L or 73,000 cubic feet(ft³)] passes the monitoring point Approximately 75 to 110 grab samples can be composited in the sample carboy with sufficient grab sample volume repeatability
- Acceptable Decision Error Rates for Statistical Sampling Design
 - Variability is not known for flow-paced monitoring Therefore, decision error rates cannot be estimated Sampling design was based, instead, on flow and professional judgement

²⁸ Appropriate action levels and standards for volume-weighted, 30-day moving averages or 1 calendar-day arithmetic averages, are specified for individual contaminants in RFCA

²⁹ AoIs are specified in Table A-26 in Appendix A to this section

³⁰ POE monitoring stations for Segment 5 are designated in Figure 2-4

³¹ Mitigating action may include, but not be limited to, the following examples 1) immediate action to halt a discharge or contain a spill, or 2) use of the source location decision rule to seek out and mitigate upstream contaminant sources

³² RFCA may actually specify consequences for an exceedance of any action level (not just those for AoIs) at any location within the segment (not just at the consensus monitoring points) This decision rule presents the consensus decision rule that drives our monitoring activities It is an implementation, rather than a reiteration, of RFCA

The decision error types and consequences for Segment 5 are presented in Table 2-12

Statisticians from the Pacific Northwest National Laboratory (PNNL) evaluated sampling protocol designs based on the decision error limitations shown in Table 2-12, but historical data were inadequate to determine the number of samples needed to meet these decision error limitations³³ Therefore, the statistical design team recommended a pilot study or alternatively that the initial design be based on flow This design should be reevaluated (vs Table 2-12) after flow-paced data become available

Table 2-12
Decision Error Types and Consequences in Segment 5

Error Type	Consequences
Failure to determine that an exceedance has occurred	If the true average concentrations of AOIs are above RFCA action levels but data fail to detect this, the Site may not be compliant with RFCA
Incorrect determination that an exceedance has occurred	The Site would be required to provide notification, planning, a schedule, and response action that consumes limited resources when no exceedance had actually occurred, and the response would not be justifiable

The decision error limitations shown in Table 2-13 were not used to design and specify the FY98/FY99 monitoring targets They are retained here, however, for use in future sampling designs when variability becomes known for the flow-paced sampling method Note that the decision error limitations shown in Table 2-13 are based on the assumption that failure to detect an exceedance is more important than falsely reporting an exceedance when no exceedance has occurred The DQO team discussed this issue, but consensus was not achieved When flow-paced data become available and the sampling design is reevaluated, this issue will be resolved

³³ Actually, the statisticians were able to provide sample sizes based on historical data variability, but these sample sizes were impractically large due to the high variability in historical sampling methods (storm flow samples taken from the rising limb of the hydrograph) Because the FY98/FY99 monitoring at POEs will use, in part, the flow-paced method (with much lower variability expected) sample sizes based on historical variability would be inappropriate

Table 2-13
Proposed Decision Error Limit Design Constraints for Segment 5 Monitoring

"Assumed-True" Parameter Value	Correct Decision	Acceptable Probability of Making an Incorrect Decision
0.1 x action level	Does not exceed action level	0.05
0.5 x action level	Does not exceed action level	0.10
0.5 to 1 x action level	Does not exceed action level	Gray region No probability specified
2 x action level	Exceeds action level	0.05
4 x action level	Exceeds action level	0.01

Note

This table is retained for future use, but was not used for FY98/FY99 decision rules

Monitoring Targets

The recommended monitoring design for the Site is to take samples for FY98/FY99, as specified in Table 2-14, and analyze each sample for the Segment 5 AoIs specified in Table A-27, attempting to take no less than one sample per quarter and no more than four sequential carboy samples per month from each of the three monitoring points for each month. The ideal sampling rate is one 15-L sample carboy for each 500,000 gallons of stream flow, and each 15-L sample carboy should comprise approximately 50 flow-paced grab samples.

Table 2-14 presents the number of samples per month recommended by statisticians at PNNL. There are both practical and statistical advantages to this sample allocation design. Averaging a larger number of samples is more expensive, but it protects the Site from regulatory action in response to a spurious nonrepresentative monitoring result.

There are secondary advantages to this monitoring plan. A larger number of samples allows for estimates of variability that can be used to refine the monitoring plan over time. The monitoring program specified here is a technically defensible approach that represents a compromise between a statistical design, a design based on professional judgement, and a design based on budgetary constraints. This design will generate data that are representative of actual contaminant levels and loads.

This design is consistent with the intent of the 30-day moving average specified in RFCA but allows some flexibility. Where there is no significant flow, there may be no samples completed within a 30-day period, and where the flows, loads, and variability are expected to be higher, sample numbers are also higher. Note that flow-paced monitoring will

continue during dry periods, even though flows may be so low that it takes more than 30 days to fill the composite sample carboy

Table 2-14
Monitoring Targets (Annual Number of Composite Samples) for Segment 5 POEs

	SW093	GS10	SW027
Month	Number of Samples		
October	3	3	0
November	4	3	0
December	2	1	1
January	2	1	0
February	2	2	0
March	4	4	1
April	4	4	4
May	4	4	4
June	4	4	4
July	2	3	0
August	2	2	0
September	3	3	1
Annual Total	36	34	15

Note Total samples for all 3 stations = 85

Alternative Minimum Required Monitoring

Although one sample per month would be adequate to demonstrate the Site's compliance status to EPA or CDPHE, there is a significant chance of declaring a false exceedance associated with smaller sample sizes. However, if budgets and priorities make the possibility of regulatory action preferable to the expense of the recommended sample sizes, then the Site may elect to gather samples as specified in Table 2-14 but analyze only one composite of those independent and sequential samples per month per station, and then perform additional analyses only if an exceedance is suggested in the composite and the historical mean for that AoI is below the action level at that monitoring station.

Several planning assumptions were adopted to estimate the minimum monitoring requirements for this high risk approach:

- Only one exceedance will be established for a single AoI at all three POEs in Segment 5, and the mitigation plan in response to that exceedance will establish increased work scope but no additional monitoring.

- Based on statistical evaluation, only Pu will exceed its action level. Thus, in the first month, Pu would incur one analysis from each station. No verification analyses would be performed because the historical average is greater than the action level. Therefore, the exceedance does not cause a change in the number of analyses during the first month.
- After the initial exceedance, only one sample per station per month would be taken.
- This one sample would be a composite that does not exceed a new criterion established by the mitigation plan.

The resulting projection of absolute minimum analytical requirements for Segment 5 is detailed in Table 2-15³⁴

Table 2-15
Estimated Minimum Segment 5 Action Level Monitoring Requirements

Analyses	Sampling Protocol
Plutonium	$3(1+11) = 36$
Uranium	$3 \times 12 = 36$
Americium	$3 \times 12 = 36$
Beryllium	$3 \times 12 = 36$
Chromium	$3 \times 12 = 36$
Silver	$3 \times 12 = 36$
Cadmium	$3 \times 12 = 36$
Hardness	$3 \times 12 = 36$
pH	Continuous
Conductivity	Continuous
Turbidity	Continuous
Nitrate	Continuous
Flow	Continuous

³⁴ Note that this approach is contrary to the approach negotiated by the DOE, RFFO and approved during development of the IMP. This approach would incur significant risk of exceedances and regulatory response actions. Although Segment 5 may not be subject to penalties for exceedances, there would be increased risk of failure to notify, plan, schedule, and implement mitigating actions due to the much larger number of exceedances resulting from natural variability of single sample preparations and analytical results (rather than averages), combined with reduced resources and a smaller work force.

2.5 Monitoring Objectives for Terminal Detention Pond Discharges and Water Leaving the Site

This section covers all surface water monitoring in streams leaving the eastern Site boundary (Indiana Street). This water is designated as Stream Segment 4a and/or 4b. This water is first monitored prior to discharge from the terminal ponds. Monitoring for RFCA compliance in Stream Segment 4 takes place at the terminal pond outfalls, and in both Woman and Walnut Creeks, near Indiana Street (RFCA POCs). Additional non-POC monitoring at Indiana Street has been identified by the working group and is described at the end of this section.

2.5.1 PredischARGE Monitoring

As the Site moves into its accelerated cleanup, there is a possibility that new or increased levels of pollutants will be introduced into the pond systems from activities in the Industrial Area. The other monitoring objectives in this IMP are focused on specific analytes and indicators of greatest concern. Flow-paced monitoring of those parameters for pond inflows is comprehensive. However, some unusual contaminant could be overlooked by the other monitoring objectives. It is important, therefore, to include a comprehensive analysis at some point, even when the historical data show no previous exceedances. The single sample predischARGE monitoring is the least expensive method for including a comprehensive analytical suite in this IMP.

Under normal batch pond operations, nearly all water produced at the Site (including surface water runoff, treated effluents, and various approved process waste streams) is detained in one of three terminal ponds. The terminal ponds serve as the last control³⁵ point for the water before it leaves the Site.

For these reasons, predischARGE monitoring is needed for a full range of constituents, including radionuclides, inorganics, and organics. Samples should represent the water to be discharged (i.e., grab samples should be depth integrated where applicable, and addition of water to the discharge should be minimized after the grab sample is taken). If the State of Colorado believes that the first sample is not representative of the discharge, the State may request, and the Site will provide, one additional predischARGE sample if the discharge has not yet begun, or a during-discharge sample if the discharge is not yet complete. However, because of dam safety, the Site has sole discretion to determine the schedule for discharges, independent of any action the State may take with regard to predischARGE monitoring. If the predischARGE monitoring suggests an exceedance of a contaminant that is also monitored by flow-paced methods, the parties recognize that the flow-paced methods would be more representative of the discharge compliance status.

³⁵ The Site's control over impounded water is quite limited. There are no treatment options readily available, and the detention time is limited by the capacity of the pond and the rate of influx from precipitation and other sources.

It is the intention of the parties that for predischARGE monitoring the Site will perform the sample collection and that CDPHE will perform the laboratory analysis and reporting functions of the completed analytical data to the Site

Data Types and Frequency

It is estimated that a total of 8-10 predischARGE samples will be taken annually from the ponds in the Walnut Creek drainage and one sample per year is expected to be taken from Pond C2 in the Woman Creek drainage CDPHE will analyze the samples for an extensive list of constituents, including inorganics, metals, volatile organics, semivolatile organics, radiologic parameters, herbicides, and pesticides The final list will be detailed in CDPHE's annual monitoring plan

This predischARGE monitoring is limited to Ponds A4, B5, and C2, or any other pond functioning as a terminal pond (e g , Pond A3 during construction in Pond A4) Samples are intended to be taken far enough in advance of the discharge so that isolation, containment, flow-paced compliance monitoring (at the terminal pond outfall POCs), or other actions can be taken to mitigate an exceedance, but near enough to the time of discharge that the sample is representative of the discharge It is the intent of all parties that sampling will be performed so that results are known prior to discharge

Decision Statement

IF PredischARGE monitoring results suggest apparent exceedances of the applicable stream standards—

THEN CDPHE may notify the Site of additional AoIs for that discharge

- The Site would then perform flow-paced POC monitoring for the additional AoI(s) during the discharge, as part of the Segment 4 compliance monitoring (see Section 2 5 2), and
- The Site may evaluate other water management options, including but not limited to treatment, storage, or disposal, rather than immediate discharge

It should be noted that the results of predischARGE monitoring can only indicate an *apparent* exceedance because

- The water sampled is impounded and not discharged at the time of sampling (the predischARGE sampling protocol applies to water to be discharged), and

- The single grab predischage sample does not necessarily reflect the quality associated with a 30-day moving average, against which nearly all standards are measured

If an apparent exceedance is reported, DOE, RFFO has the responsibility to decide management alternatives. It is the intent of the parties that predischage monitoring is not enforceable under RFCA, but it will be performed as a prudent management practice that all parties endorse.

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - Predischage monitoring is a routine practice. It is unlikely that a discharge would occur without predischage monitoring.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - The parties intend that only one sample will be taken. No statistical sampling design is needed.

Monitoring Targets

Monitoring analyses to be performed by CDPHE are shown in Table 2-16.

Table 2-16
Predischage Monitoring Targets (Number of Samples/Analyses)

Analytical Parameter	Average Analyses per Month
Volatile organic analyses (502.2)	0.8
Chlorinated herbicide analyses (515.1)	0.8
Semivolatiles (525.2)	0.8
Selected Hazardous Substance List metals (total/total recoverable)	0.8
Selected Hazardous Substance List metals (dissolved)	0.8
Total dissolved solids	0.8
Total suspended solids	0.8
Nitrate/Nitrite as N	0.8
Nitrite as N	0.8

Table 2-16
(continued)

Analytical Parameter	Average Analyses per Month
Total phosphate	0 8
Orthophosphate	0 8
Ammonia	0 8
Sulfide	0 8
Gross alpha	0 8
Gross beta	0 8
Plutonium/uranium/americium	0 8
Tritium	0 8
pH	0 8
Dissolved oxygen	0 8
Conductivity	0 8
Totals	16 8

Note Numbers of analyses are based on historical pond discharge operations

2.5.2 Stream Segment 4/Point of Compliance Monitoring

RFCA provides specific standards for Walnut and Woman Creeks below the terminal ponds (Segment 4). These criteria and the responses to them are different than the criteria and actions associated with Segment 5. This section deals only with monitoring discharges from the terminal ponds into Segment 4 and the additional points of compliance for Segment 4 at Indiana Street. Terminal pond discharges will be monitored by POCs GS11, GS08, and GS31. Walnut Creek will be monitored at Indiana Street by POC GS03. Woman Creek will be monitored at Indiana Street by POC GS01. These locations are shown on Figure 2-4.

With the completion of the Woman Creek Reservoir, located just east of Indiana Street and operated by the city of Westminster, all Woman Creek flows will be detained in cells of the new reservoir until the water quality has been assured by monitoring of Site discharges via Woman Creek at Indiana Street (at GS01). Reservoir water will then be pumped from Woman Creek Reservoir into the Walnut Creek drainage below Great Western Reservoir.

In the past, the majority of natural flow in Woman Creek was diverted to Mower Reservoir and did not exit the Site via Woman Creek. This is no longer the case, the Mower Ditch headgates have been upgraded, and all flows in Woman Creek will leave the Site via Woman Creek (at GS01) and enter the Woman Creek Reservoir. In the past, Pond C2 (located off channel in the Woman Creek drainage) was predischarged sampled and subsequently pumped from Woman Creek into the Walnut Creek drainage on Site. Currently, the Site pump discharges Pond C2 directly into Woman Creek (at GS31), which then flows to the Woman Creek Reservoir.

There is concern that meeting standards for radiologic parameters in Pond C2 discharge does not adequately demonstrate that all water leaving the Site via Woman Creek and entering the Woman Creek Reservoir is meeting the radiologic standards. Other Woman Creek water (combined with Pond C2 or flowing in the absence of any Pond C2 water) will enter the Woman Creek Reservoir. This is the basis for setting an additional RFCA POC for Woman Creek at Indiana Street (GS01) for those radiologic contaminants that could be directly attributable to the Site (i.e., not naturally occurring).

A similar point of compliance, GS03, will be established at Walnut Creek and Indiana Street. Although the Walnut Creek drainage is not undergoing operational changes like those in Woman Creek, it is possible that contaminated overland runoff or landfill drainage may enter Walnut Creek below the terminal pond monitoring points (GS11 and GS08), yet upstream of Indiana Street.

Data Types and Frequency

- RFCA AoIs, as sampled for Stream Segment 4 terminal pond discharges (see Table A-27 in Appendix A to this section)
- Isotopic Pu, Am, and tritium at Indiana Street POCs
- Source(s) of the water sampled. Monitoring at Indiana Street POCs GS01 and GS03 calls for samples to be segregated based on water origin (natural creek flows or terminal pond discharges commingled with natural flows)
- Samples collected will be continuous flow-paced composites
- Flow-paced monitoring is maintained at all times for all five POCs in Segment 4, even though no samples are anticipated from terminal pond stations except during planned pond discharges

Terminal pond discharges currently occur approximately once per year for Pond C2 and nine times per year for Ponds A4 and B5. Since the DQO process targeted 3 samples per discharge, terminal pond POCs currently target 30 composite samples to be collected annually.

During FY97, all routine North and South Walnut Creek water was discharged from Pond A4 (Pond B5 was pump transferred to Pond A4 with the exception of IDLH operations requiring direct discharge of Pond B5, see Section 2.2.1)³⁶. Therefore, sampling protocols will be modified for FY98/FY99 such that the number of continuous flow-paced composite samples to be collected

³⁶ It is expected that Pond B5 will be periodically direct discharged to Walnut Creek using the new outlet works. This discharge scenario is subject to agreement by the concerned parties.

annually for discharge from either Pond A4 or Pond B5 will be comparable to FY97. For fiscal years 1993 through 1997, the total combined discharge volume for Pond A4 and Pond B5 was 687 thousand gallons (Mgals) in 43 discharge batches, or 16 Mgals per discharge on average. Targeting three composite samples per discharge gives one composite sample per 5.3 Mgals of discharge volume. This modification will preserve the targeted sampling frequencies (based on discharge volume) while maintaining effective cost controls (based on total sample costs). For planning purposes, 8 samples will be collected from Pond A4, and 19 from Pond B5, resulting in the collection of the targeted 27 composite samples (see Table 2-19). However, this sample planning is dependent on the routing for the WWTP effluent. Any future changes in the management of Walnut Creek water could result in sampling protocol modifications while preserving the initial intent of the DQO process. For Pond C2 discharges, three composite samples will be collected per discharge, regardless of volume.

The Indiana Street stations would generate the same number of samples during discharges, plus additional samples from storm runoff and base flow between discharges. GS01 will collect three samples for the one expected Pond C2 discharge, and storm runoff and base flow samples based on average annual volumes. During storm runoff and base flow, the target is one sample per 500,000 gallons, with a maximum of three samples during any one month (see Table 2-19). GS03 will collect the targeted 27 samples during Pond A4 and Pond B5 discharges (GS03 will collect the same number of composite samples as the terminal pond POCs for each discharge). During storm runoff and base flow periods between discharges, GS03 will target two samples per period. The goal is to have two analytical results for any 30-day period for averaging purposes. The Site reserves the right to combine samples of the same flow pacing to save resources, as long as two sample results are available for any 30-day period. This sample frequency increase from FY97 for GS03 is a result of sampling protocol changes due to the occurrences of NSQ samples in FY97.

POC monitoring will be confined to Stream Segment 4 only, as represented by samples taken from the terminal pond discharges at GS11, GS08, and GS31, and the Indiana Street monitoring stations (GS01 and GS03). Table 2-17 shows the associations between monitoring locations and station designators.

Table 2-17
POC Monitoring Station Designators for Segment 4

Pond A4	GS11
Pond B5	GS08
Pond C2	GS31
Walnut Creek at Indiana Street	GS03
Woman Creek at Indiana Street	GS01

Decision Statement

- IF The volume-weighted 30-day moving average³⁷ for any AoI in Stream Segment 4, as represented by samples from the specified RFCA POCs (i.e., terminal pond discharges and Indiana Street) exceeds the appropriate RFCA standard—
- THEN RFCA requires that DOE, RFFO inform regulators within 15 days of DOE, RFFO gaining knowledge (not just a suspicion) that an exceedance (verified) has (actually) occurred
- Notify EPA, CDPHE, and either Broomfield or Westminster, whichever is affected,
 - Submit a plan and schedule to evaluate for source location, and implement mitigating action if appropriate, and
 - The Site may receive a notice of violation

Note that for the Indiana Street POCs, the only compliance monitoring to be performed is for Pu, Am, and tritium activity as measured at GS01 or GS03³⁸

³⁷ The 30-day average for a particular day is calculated as a volume-weighted average of a "window" of time containing the previous 30-days that had flow. Each day has its own discharge volume (measured at the location with a flow meter) and activity (from the sample carboy in place at the end of that day). Therefore, there are 365 30-day moving averages for a location that flows all year. At locations that monitor pond discharges or have intermittent flows, 30-day averages are reported as averages of the previous 30 days of greater than zero flow. For days where no activity is available, either due to failed laboratory analysis or NSQ for analysis, no 30-day average is reported.

³⁸ GS01 and GS03 are the POC monitoring stations for Woman Creek at Indiana Street, and Walnut Creek at Indiana Street, respectively.

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - The Site will attempt to gather at least one sample representative of each pond discharge event, and multiple sequential samples may be taken. Flow-proportional monitoring will be maintained at all times but may not be effective during dry periods when evaporative losses would invalidate the data, or when samples are inadequate for analysis due to a variety of operational problems.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - The decision error types and consequences for Segment 4 are presented in Table 2-18.

Table 2-18
Decision Error Types and Consequences in Segment 4

Error Type	Consequences
Failure to determine that an exceedance has occurred	Potential for downstream water quality impacts
Incorrect determination that an exceedance has occurred	The Site would be required to provide notification, planning, a schedule, and response action that consumes limited resources when no exceedance has actually occurred, and the response would not be technically justifiable. The Site may also be subject to inappropriate fines or penalties or other regulatory action.

CDPHE and EPA representatives on the DQO team favored a simple decision rule that would be easier to explain to a concerned public. This led to a decision rule that placed equal emphasis on false alarms and failures to detect exceedances. The statistical design team recommended that the initial design be based on flow, and that this design should be reevaluated after flow-paced data become available.

Monitoring Targets

Table 2-19 presents monitoring targets for Segment 4 POCs. The overall strategy is to sample each discharge as stated in the *Data Types and Frequency* text above. This plan assumes 8 samples per year from Pond A4, 19 samples from Pond B5, and 3 samples from Pond C2. There is no storm or base flow immediately below the dams. At Walnut Creek

and Indiana Street (GS03), the Site assumes that 27 samples will be collected annually during discharges from Ponds A4 and B5, and two samples of storm runoff and base flow during the periods between discharges (approximately 20 samples). The Site will attempt to schedule discharges from Ponds A4 and B5 concurrently. Therefore, approximately 10 discharge cycles per year will occur in Walnut Creek. At Woman Creek and Indiana Street (GS01), the Site plans to take three samples during one Pond C2 discharge per year and volume based number of samples each month for storm runoff and base flow periods. The increase in storm runoff and base flow samples at GS01 is due to the new routing of Mower Ditch water to Woman Creek Reservoir and the corresponding increase in volume to be monitored. Note that the analyte lists for the terminal pond discharges are different than the analyte lists for the Indiana Street POCs.

Table 2-19
POC Monitoring Targets (Number of Samples/Analyses) for Segment 4 POCs

Time Period	Pond			Walnut Creek at Indiana Street	Woman Creek at Indiana Street	Total Number of Samples
	A4	B5	C2			
During Discharge	8	19	3	27	3	60
Storm and Base Flow						
January	--	--	--	1	2	3
February	--	--	--	1	2	3
March	--	--	--	2	3	5
April	--	--	--	2	3	5
May	--	--	--	2	3	5

December	--	--	--	1	2	3
FY Totals	8	19	3	47	28	105

Note

-- = Not applicable
FY = Fiscal year

2.5.3 Non-POC Monitoring at Indiana Street

The State of Colorado has proposed to conduct this non-POC monitoring as a prudent management action, and it is the intent of the RFCA parties that no enforcement action will be taken on the basis of this monitoring. There are several reasons to monitor for certain possible contaminants and nutrients in the water leaving the Site in both drainages. The actions to be taken on the basis of this monitoring are variable and may not be known until the monitoring results are available.

The CWQCC is moving toward waste load allocations for all segments of the Big Dry Creek drainage. Nutrient loadings generated by the Site are carried off Site via Walnut Creek, which either can bypass the Great Western Reservoir or be directed into the reservoir. Water bypassing the reservoir enters Segment 1 of Big Dry Creek, which then flows into the South Platte River. The Broomfield water replacement project will result in changes to the quantity and quality of water that could enter Great Western Reservoir. For these reasons, it will be necessary to monitor nutrient loads leaving the Site under all three of these conditions:

- Water leaving the Site via Walnut Creek that is 100% Site pond discharge (either originates as surface water on Site or is used and potentially contaminated by the Site before discharge from terminal ponds),
- Water leaving the Site via Walnut Creek is 100% stream flow and does not include pond discharge, and
- Water leaving the Site via Walnut Creek that is a mixture of Site discharge and stream flows

With the changes in flow configuration in the Woman Creek drainage, there is a need to monitor to determine new ambient levels for various analytes at monitoring station GS01. The results of these analyses will be used to determine what changes in water quality, if any, have occurred as a result of the new flow configuration.

Data Types and Frequency

The complete list of analytes (analyzed by CDPHE) are given in Table 2-20. The real-time parameters will be collected by the Site. Note that pH and temperature are needed to calculate un-ionized ammonia, and that the parties intend to drop monitoring for Be, Cd, Ag, and Cr in the FY98 monitoring plan, unless FY97 monitoring results provide reasonable cause for concern. Nutrient analysis samples are grab samples. Un-ionized ammonia analyses are for samples from Walnut Creek at Indiana Street.

The source(s) of water at these locations during any sampling event must be identified.

Sample collection frequency will be as follows

- Walnut Creek
 - Five per year for 100% Site effluent (pond discharges),
 - Five per year for mixed effluent and natural stream flow, and
 - Five per year for 100% natural stream flow
- Woman Creek
 - Five per year not during Pond C2 discharge, and
 - One per year during Pond C2 discharge

Table 2-20
Non-POC Monitoring Requirements (Number of Samples/Analyses)
at Indiana Street

Analyte	Number of Samples
Total ammonia	21
Nitrite	21
Nitrate	21
Total phosphate as P	21
Orthophosphate	21
Be, Cd, Ag, Cr	21
Isotopic uranium	21
pH	Continuous 15 min intervals
Temperature	Continuous 15 min intervals
Conductivity	Continuous 15 min intervals
Flow	Continuous 15 min intervals

Notes

Five samples at each of the three flow mixtures in Walnut Creek, plus one Woman Creek sample during Pond C2 discharge and five samples when Pond C2 is not discharging $(5 \times 3) + 1 + 5 = 21$ CDPHE will take their own grab samples independently for all nutrients, four metals, and U

Ag = Silver
 Be = Beryllium
 Cd = Cadmium
 CDPHE = Colorado Department of Public Health and Environment
 Cr = Chromium
 min = Minute
 P = Phosphorous
 POC = Point of compliance
 U = Uranium

Non-POC monitoring is limited to Stream Segment 4, as represented by samples taken from Walnut Creek at Indiana Street and Woman Creek at Indiana Street (GS03 and GS01, respectively)

At different times, the water flowing off Site has differing composition of Site and natural stream flow. Samples will be scheduled so as to be representative of this variable composition.

Decision Statement

IF Concentrations or loadings of specified contaminants in Woman Creek exceed their 95% UTLs—

THEN CDPHE will notify the Site and cities, and the Site may propose a change in ambient standards

No formal action has been identified as being dependent on nutrient monitoring of Walnut Creek at Indiana Street. The data may or may not be used in determining a waste load allocation for the Site in the future.

Acceptable Decision Errors

- Confidence that Significant Events are Physically Sampled and Representative
 - No special measures are needed beyond standard operating procedures
- Acceptable Decision Error Rates for Statistical Sampling Design
 - To be decided after variability is determined through FY97 monitoring

Monitoring Targets

One objective of FY97 nutrient load monitoring was to establish the variability of the data so that FY98 monitoring can be statistically designed. Three samples would be the absolute minimum required to estimate variability. Five samples for each parameter are planned. This monitoring is presented in Table 2-20.

2.6 Off-Site Monitoring Objectives: Community Water Supply Management

Contaminants generated by operations at the Site may have migrated off Site and impacted the downstream reservoirs. In addition, D&D activities at the Site may increase the risk of

environmental contaminant release. The potential for the public to be exposed to contaminants originating from the Site that can impact the community water supplies engenders public concern. Government officials in the downstream communities must respond to this public concern with adequate and timely monitoring data.

The ultimate decision regarding the management of community water resources rests with the affected community, however, monitoring data generated by other entities, such as CDPHE and the Site, are used to assess potential impacts, demonstrate acceptable water quality, and allay consumer concerns. These data are critical inputs for operational decisions.

2.6.1 Monitoring Uncharacterized Discharges

This monitoring would normally be required only if monitoring specified under the previous decision rules is not performed in accordance with the sampling and analysis protocols, e.g., POC and POE monitoring at Indiana Street, or if flow leaving the Site exceeds the capacity of the downstream ditches or reservoirs.

If surface water of unknown quality (unmonitored) leaves the Site, it is necessary to demonstrate that the water quality is acceptable to the downstream users. Examples include:

- Flow that has the potential to exceed the capacity of the Walnut Creek Diversion Ditch and enter Great Western Reservoir instead of being diverted around the reservoir, and
- Water quality in downstream waters that may have been impacted by unmonitored effluent from the Site.

Data Types and Frequency

- Flow at the following monitoring locations
 - Pond A4 North Walnut Creek, GS11,
 - Pond C2, GS31,
 - Pond B5 South Walnut Creek, GS08,
 - Woman Creek at Indiana Street, GS01,
 - Walnut Creek at Indiana Street, GS03, and
 - McKay Ditch (currently monitored by temporary source location monitoring station GS35)

Flow from these stations is needed to evaluate

- The potential for Walnut Creek to exceed the capacity of the Walnut Creek Diversion Ditch [estimated at 40 cubic feet per second (cfs)] and spill over into Great Western Reservoir, and
- The relative contribution of various sources (ponds, storm drainages) to the total flow leaving the Site

After the release event, water quality data may be evaluated in combination with flow data to estimate the total impact. Note that the flow data will already be available from monitoring performed under other decision rules

- Water quality as follows
 - Analytes are shown in Table 2-21
 - Note: Constituents appearing on the "Short List" represent a minimum analyte list for all unplanned releases or discharges. Some or all of the constituents on the "Long List" may be necessary depending on the nature of the event, the source of the release, and the receiving water. The composition of either list may change depending on activities at the Site at the time of the event. Samples should be taken, but not necessarily analyzed, for all possibilities.

Table 2-21
Off-Normal Discharge Monitoring Inputs

Constituent Group	Short List	Long List
Radionuclides	Pu, gross alpha/beta (rapid turnaround indicator)	Gross alpha/beta, Pu, Am, U (isotopic), tritium
Physical properties and general water quality measurements	pH, temperature, turbidity, TSS, conductivity or TDS	pH, temperature, turbidity, TSS, conductivity, TDS, hardness, alkalinity, fluoride, chloride, sulfate
Nutrients	Nitrate + nitrite	Nitrate, nitrite, ammonia (total and un-ionized), orthophosphate, total phosphorus
Organics	None	VOCs (EPA 524.2)
Metals	None	All metals having stream standards (As, Be, Cd, Cr, Cu, Fe, Pb, Mn, Hg, Ni, Se, Ag, Zn)

Notes

Ag = Silver	Ni = Nickel
Am = Americium	Pb = Lead
As = Arsenic	Pu = Plutonium
Be = Beryllium	Se = Selenium
Cd = Cadmium	TDS = Total dissolved solids

Cr	=	Chromium	TSS	=	Total suspended solids
Cu	=	Copper	U	=	Uranium
Fe	=	Iron	VOC	=	Volatile Organic compound
Hg	=	Mercury	Zn	=	Zinc
Mn	=	Manganese			

- Action levels

- Action levels would be the applicable CWQCC standard for the potentially impacted downstream segment (Segments 4a/b and 5)

- Sampling locations

Specific locations are event-driven, but may include

- Walnut Creek at Indiana Street, GS03,
 - Woman Creek at Indiana Street, GS01, or
 - Great Western Reservoir (only necessary if release of surface water enters Great Western Reservoir)

- Sampling frequency

- Event driven, only when uncharacterized water leaves the Site

- Sample type

- Walnut and Woman Creeks at Indiana Street If flow-paced composite sampling as specified under POC monitoring cannot be conducted, then grab samples will be collected as soon as the event is detected and every 4 hours thereafter until continuous monitoring is reestablished or the event terminates
 - Reservoirs Representative reservoir sampling will be conducted in accordance with the event and as agreed by the impacted parties At a minimum, a surface composite sample, consisting of grab samples collected at various points in the reservoir, and a depth composite sample will be collected 48 hours after the event

Geographically, this monitoring objective is bounded by the Walnut and Woman Creek basins, from the western Site boundary to the main stem of Big Dry Creek However, the downstream communities are primarily concerned about the negative impact of contaminants leaving the Site on downstream reservoirs and water supplies, thus the monitoring locations of interest are

- Woman Creek at Indiana Street, GS01,

- Walnut Creek at Indiana Street, GS03,
- Great Western Reservoir,
- Woman Creek Reservoir, and
- Mower Reservoir

For this decision, monitoring would only be required when water of unknown quality leaves the Site. Under routine operations wherein surface water is under full management control of the Site, dam safety is not threatened, and POC monitoring is conducted as specified under Section 2.5.2, this monitoring is not needed.

Decision Statement

IF Surface water of unknown or unacceptable quality leaves the Site

THEN The affected community will take appropriate protective measures until analytical data show that water quality is acceptable for the intended use

For example, in the event of a contaminant release to Woman Creek Reservoir, Westminster might refrain from discharging water downstream until water quality has been analyzed and determined to be acceptable.

Acceptable Decision Errors

Because this monitoring is event-driven, decisions regarding necessary and sufficient monitoring must be based on the nature of the event. Samples may be single grab samples, location composites, or time composites. Statistically-based sample sizes will not be used for development of this FY98/FY99 monitoring plan.

Monitoring Targets

For planning purposes, no uncharacterized discharges are projected for FY98/FY99. If such a discharge does occur and this monitoring is needed, then the number and type of samples would be determined on a case-by-case basis.

2.6.2 Community Assurance Monitoring

RFETS' past mission as a nuclear weapons production facility, the nature of the contaminants, the history of releases and accidents, and the geographic and hydrologic relationship of the Site to the neighboring municipalities have made it necessary for the communities to reassure residents that their environment is safe. The level of concern fluctuates with activities at the Site but may be expected to continue as long as environmental contamination and special nuclear materials are present at the Site. Citizens' concerns are more effectively addressed by a routine monitoring

program to measure the contaminants of concern at the locations of concern, than by institutional controls, modeling, and on-Site monitoring. The minimal community monitoring needed to provide this assurance is relatively inexpensive and demonstrates a community commitment on the part of DOE, RFFO. This community monitoring and Site monitoring are discussed at the Quarterly Information Exchange Meetings. The DOE, RFFO has also sponsored a dose reconstruction study for the Site.

Adequate and timely information regarding the impact of the Site on the neighboring environment is needed so that the communities can respond to citizens' concerns and the Site can foster a credible public image. Inadequate monitoring results in poor public relations, impaired trust, increased public resistance to proposed activities at the Site, *and increased mandatory monitoring*. The necessity for repeated public meetings and clean-up delays due to negative public comment may increase costs of operating the Site.

Data Types and Frequency

- Sampling locations
 - Since the completion of the Standley Lake Protection Project and the Great Western Reservoir Replacement Project, which were designed to protect the potable water supplies, routine monitoring of the municipal treatment and distribution systems is no longer warranted. However, Great Western Reservoir is still used as an irrigation supply, and the fact that the reservoir is considered to be unsuitable for potable use raises questions on the part of irrigation customers. Ongoing assessment is needed to address these question.
 - For FY98/FY99, Great Western Reservoir is the only sampling location needed.
- Sample types
 - Quarterly depth-integrated composite samples are adequate to characterize the contaminant concentration in Great Western Reservoir.
- Sampling methods
 - City personnel routinely conduct sampling in Great Western Reservoir and will collect the necessary samples for this objective as part of Broomfield's sampling program.
 - A sampling protocol acceptable to all parties will be developed and documented.

- Analytical methods
 - Analytical methodology must be adequate to provide detection limits comparable to those reported by CDPHE since 1992—approximately 0.003 picocuries (pCi)/L for treated water and 0.006 pCi/L for raw water

- Analyte list

This monitoring is limited to radionuclide contamination that is potentially attributable to the Site

- Pu-239/240,
- Am-241,
- U, isotopic (at least U-233/234 U-238), and
- Tritium

The total number of samples needed for this monitoring objective would be four samples per year for FY98/FY99

The hydrologic regime for the Great Western Reservoir will change over time as the cities' irrigation and reuse projects are implemented. Sampling locations, types, and frequencies will be reevaluated to reflect these changes.

Decision Statement

- | | |
|------|--|
| IF | The potential for public exposure to contaminants attributable to the Site causes reasonable concern in the neighboring communities— |
| THEN | Monitoring to quantify contaminant concentrations and provide the necessary information must be performed |

The response to a significant change in contaminant levels would be a different decision. The monitoring objectives described in previous sections are designed to prevent increased concentrations in the community drinking water systems. These community assurance monitoring data are used to address routine inquiries and to respond to occasions of unusual public concern. The data have been needed in the past and should be considered in future planning.

Acceptable Decision Errors

Sufficient sampling and analysis must be performed to provide credible assurance that community water quality is adequately monitored and understood. A high level of confidence that the monitoring meets the desired objective is necessary. Because the type of monitoring involved is inconsistent with multiple samples, the required certainty must be achieved through appropriate sampling procedures, adequate sample volumes, laboratory quality control, and good analysis validation protocols.

Monitoring Targets

Monitoring requirements for this section are presented in Table 2-22

Table 2-22
Monitoring Targets (Number of Samples/Analyses) for Community Assurance Monitoring

Analyte	Analyses for FY98/FY99	
	Great Western Reservoir (Analyses per year)	Total
Pu-239/240	4	8
Am-241	4	8
U, isotopic ³⁹	4	8
Tritium	4	8

Notes

Am = Americium

FY = Fiscal year

Pu = Plutonium

U = Uranium

Table I-Conventional Pollutants

Total suspended solids (TSS)	pH
Total dissolved solids (TDS)	Total Kjeldahl nitrogen
Chemical oxygen demand (COD)	Nitrate plus nitrite
5-day biological oxygen demand (BOD5)	Dissolved phosphorus
Oil and grease	Total ammonia plus organic nitrogen
Fecal coliform	Total phosphorus
Fecal streptococcus	

Table II-Organic Toxic Pollutants in Each of Four Fractions in Analysis by Gas Chromatography/Mass Spectroscopy (GS/MS)

Volatiles		
acrolein	dichlorobromomethane	1,1,2,2-tetrachloroethane
acrylonitrile	1,1-dichloroethane	tetrachloroethylene
benzene	1,2-dichloroethane	toluene
bromoform	1,1-dichloroethylene	1,2-trans-dichloroethylene
carbon tetrachloride	1,2-dichloropropane	1,1,1-trichloroethane
chlorobenzene	1,3-dichloropropylene	1,1,2-trichloroethane
chlorodibromomethane	ethylbenzene	trichloroethylene
chloroethane	methyl bromide	vinyl chloride
2-chloroethylvinylether	methyl chloride	
chloroform	methylene chloride	

Table III-Other Toxic Pollutants (Metals and Cyanide) and Total Phenols

Antimony, Total	Chromium, Total	Nickel, Total	Zinc, Total
Arsenic, Total	Copper, Total	Phenols, Total	Cyanide, Total
Beryllium, Total	Lead, Total	Silver, Total	Selenium, Total
Cadmium, Total	Mercury, Total	Thallium, Total	

Table IV-Conventional and Nonconventional Pollutants Required to be Tested by Existing Dischargers if Expected to be Present

Bromide	Nitrogen, Total Organic	Surfactants	Molybdenum, Total
Chlorine, Total	Oil and Grease	Aluminum, Total	Manganese, Total
Residual	Phosphorus, Total	Barium, Total	Tin, Total
Color	Radioactivity	Boron, Total	Titanium, Total
Fecal Coliform	Sulfate	Cobalt, Total	
Fluoride	Sulfide	Iron, Total	
Nitrate-Nitrite	Sulfite	Magnesium, Total	

Table V-Toxic Pollutants and Hazardous Substances Required to be Identified by Existing Dischargers if Expected to be Present

Toxic Pollutants		
Asbestos		
Hazardous Substances		
Acetaldehyde	Disulfoton	Phosgene
Allyl alcohol	Diuron	Propargite
Allyl chloride	Epichlorohydrin	Propylene oxide
Amyl acetate	Ethion	Pyrethrins
Aniline	Ethylene diamine	Quinoline
Benzonitrile	Ethylene dibromide	Resorcinol
Benzyl chloride	Formaldehyde	Strontium
Butyl acetate	Furfural	Strychnine
Butylamine	Guthion	Styrene
Captan	Isoprene	2,4,5-T (2,4,5-Trichlorophenoxy acetic acid)
Carbaryl	Isopropanolamine	TDE (Tetrachlorodiphenylethane)
Carbofuran	Dodecylbenzenesulfonate	2,4,5-TP [2-(2,4,5-Trichlorophenoxy) propanoic acid]
Carbon disulfide	Kelthane	Trichlorofan
Chlorpyrifos	Kepone	Triethanolamine dodecylbenzenesulfonate
Coumaphos	Malathion	Triethylamine
Cresol	Mercaptodimethur	Trimethylamine
Crotonaldehyde	Methoxychlor	Uranium

Hazardous Substances (Continued)

Cyclohexane	Methyl mercaptan	Vanadium
2,4-D (2,4-Dichlorophenoxy acetic acid)	Methyl methacrylate	Vinyl acetate
Diazinon	Methyl parathion	Xylene
Dicamba	Mevinphos	Xylenol
Dichlobenil	Mexacarbate	Zirconium
Dichlone	Monoethyl amine	
2,2-Dichloropropionic acid	Monomethyl amine	
Dichlorvos	Naled	
Diethyl amine	Napthenic acid	
Dimethyl amine	Nitrotoluene	
Dinitrobenzene	Parathion	
Diquat	Phenolsulfanate	

Notes

CFR = Code of Federal Regulations

Table A-25
Operational Limitations on Influent to WWTP

No person shall discharge or cause to be discharged to the sanitary sewer any stormwater, surface water, groundwater, roof runoff, subsurface drainage, cooling water, air conditioning wastewater, or any other domestic, commercial or industrial wastewater not meeting the following limitations

- 1 Must have an instantaneous pH value in the range of five (5.0) to ten (10.0) standard units
- 2 Must not contain any solid, viscous or liquid wastes which allow or may cause obstruction to the flow in a collection line or otherwise interfere with the proper operation of the WWTP. Prohibited materials include all solid objects, material, refuse, and debris not normally contained in sewage
- 3 Must not contain explosive mixtures consisting of liquids, solids, or gases which by reason of their nature or quantity are, or may be, sufficient either alone or by interaction with other substances to cause fire or explosion or be injurious in any way to the operation of the WWTP. At no time shall two (2) successive readings on an explosion hazard meter at the point of discharge into the wastewater system be more than five percent (5%), nor may any single reading be over ten percent (10%) of the lower explosive limit (LEL) of the meter. Prohibited materials include, but are not limited to gasoline, kerosene, naphtha, benzene, toluene, xylene, ethers, alcohols, ketones, aldehydes, peroxides, chlorates, perchlorates, bromates, carbides, hydrides and sulfides
- 4 Must not contain any flammable substance with a flashpoint lower than 186 degrees F
- 5 Must have a temperature between 32 degrees to 150 degrees F
- 6 Must not contain grease or oil or other substance that will solidify or become viscous between 32 degrees and 150 degrees F
- 7 Must not contain improperly shredded garbage that has not been ground or comminuted to such a degree that all particles will be carried freely in suspension under flow conditions normally prevailing in the wastewater system to which the user is connected. At all times, no particle shall be greater than one-half inch (1/2) in any direction
- 8 Must not contain gases or vapors either free or occluded in concentrations toxic or dangerous to humans or animals
- 9 Must not contain any pollutant, including oxygen demanding pollutants (BOD₅, etc.) released at a rate and/or concentration which has a reasonable potential, in the opinion of the WWTP manager, to adversely affect the WWTP (inhibition, pass-through, sludge contamination, or endangerment of the WWTP operators)
- 10 Must not contain any toxic or irritating substance which will create conditions hazardous to public health and safety
- 11 Must not contain in excess of 100 ppm of any grease or oil or any oily substance from petroleum or mineral origin, or both, including but not limited to a) cooling or

	quenching oils, b) lubrication oil, c) cutting oils, and d) non-saponifiable oils
12	Must not contain toxic or poisonous solids, liquids or gases in sufficient quantity, either singly or by interaction with other wastes, to injure or interfere with any sewage treatment process, to create any hazard in the receiving waters of the WWTP or to contaminate the sludge of any wastewater treatment process
13	Must not cause the temperature of the treatment plant to exceed 40 degrees C (104 degrees F)
14	Must not contain organic toxic pollutants, introduced by the intentional or accidental dumping of solvents, used in operations involving degreasing, surface preparation, tank washing, paint thinning, paint equipment cleaning or any other process
15	Must not contain any hazardous waste, either listed or characteristic
16	Numerical guidelines See Allowable Concentrations worksheet

Notes

C	=	Celsius
F	=	Fahrenheit
LEL	=	Lower explosive limit
ppm	=	parts per million
WWTP	=	Wastewater treatment plant

Table A-26
RFCA Analytes of Interest for Segment 5

RFCA Attachment 5, Table 1 specifies additional limitations beyond those specified here, and all RFCA Table 1 contaminant limitations are applicable. But most of those contaminant limitations are not exceeded and pose hypothetical health risks well below a 10^{-6} criterion, and are not a threat to the environment. Those contaminants do not need to be monitored. The analytes of interest (AoIs) specified here are the analytes for which monitoring funds will actually be requested.

Assumptions

These AoIs were developed and agreement achieved on the basis of the assumptions below. These assumptions allow all parties to agree that funding and resources should be focused on this relatively short list of contaminants for which there is reasonable cause to expect exceedances of RFCA standards and action levels.

- Discharges into Segment 4 will be from batch operations as currently conducted
- Sampling for Segments 4 and 5 RFCA compliance will be flow-proportional
- PredischARGE sampling by CDPHE will be comprehensive
- Cost effective analytical methods used to monitor the AoIs will also yield information about other potential, but unanticipated, contaminants
- The Site will perform tritium monitoring in Segment 4 at the Indiana Street Point of Compliance
- Any of the parties may, from time to time, identify additional AoIs for cause, for a specific discharge event. If the parties agree, additional contaminants may be added to the ongoing AoIs specified here.

Table A-26
(continued)

Segment 5 Analytes Of Interest		
The signatory parties to this plan agree that the AoIs for Segment 5 main stream channel monitoring stations are those listed below		
Radionuclides	Pu 239, 240	High level of public concern Known carcinogen Known past releases (within the past 8 years) have exceeded RFCA stream standards and action levels This provides reasonable cause to expect future releases in excess of RFCA action levels
	U 233, 234, 235, 238	Known renal toxicity Present on Site Past exceedances provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels
	Am 241	Known carcinogen Present on Site Known past exceedances provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels
Metals	Be	Known to cause berylliosis in susceptible individuals when exposed by inhalation May also cause contact dermatitis Present on Site Will be monitored as an indicator of releases from process and waste storage areas
	Cr	Physiological and dermal toxicity High level of regulatory concern due, in part to the chromic acid incident of 1989 Low levels can cause significant ecological damage
	Ag (dissolved)	Highly toxic to fish at low levels if chronic State of Colorado has temporarily removed its stream standard for silver, while under study The study has been completed, and the standard will be reinstated at the next triennial review of South Platte stream standards, if not before Used on Site only for photographic development Routinely accepted by POTWs as municipal waste, but discharge is regulated May be removed from this list later if data do not support concern

**Table A-26
(continued)**

Metals (Continued)	Cd (dissolved)	Highly toxic to fish at low levels if chronic Known human carcinogen (prostate cancer) and depletes physiologic calcium Used on Site in plating processes Monitoring data for the Interceptor Trench System (ITS) and the proposed discharge of untreated ITS waters into Walnut Creek provide reasonable cause to expect future releases in excess of RFCA action levels
	Hardness	Required to evaluate metals analyses due to its effect on solubility of these metals
Real Time Monitoring of Physical and Indicator Parameters These parameters provide real-time indication for a wide variety of regulated contaminants and are also a required component of monitoring for AolS They require no laboratory analyses and are the Site's most cost effective defensive monitoring	pH	Toxicity to humans and ecology Regulatory concern due to chromic acid incident Real-time monitoring is inexpensive and effective method of detecting acid spills such as (chromic acid or plutonium nitrate) or failure of treatment systems
	Conductivity	Conductivity is an indicator of total dissolved solids, metals, anions, and pH Real-time monitoring of conductivity is an inexpensive indicator of overall water quality
	Turbidity	Turbidity is a general indicator of elevated contaminant levels and may be correlated with Pu
	NO ₃	Past releases near RFCA stream standards and action levels upstream of ponds provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels ITS discharges are often high in nitrate and may challenge RFCA action levels
	Flow	Required to detect flow events, evaluate contaminant loads, and plan pond operations and discharges Affects nearly every decision rule and is the most commonly discussed attribute of Site surface waters

Notes

VOAs, Fe, and Mn are specifically excluded from this list The parties recognize that VOAs will not be effectively monitored at these monitoring stations, and defer to the decision rules that drive monitoring closer to the sources of VOA contamination

Aol = Analytes of interest
 Ag = Silver
 Am = Americium
 Be = Beryllium

RFCA	=	Rocky Flats Cleanup Agreement
U	=	Uranium
VOA	=	Volatile organic analysis

Table A-27
RFCA AoIs for Segment 4

Segment 4 Analytes Of Interest		
This extremely focused list of AoIs was developed and agreed upon based on the following assumptions		
<ul style="list-style-type: none"> • The Site will perform Segment 5 monitoring for the AoIs described in Table A-26 • CDPHE will perform comprehensive monitoring, including tritium, for the predischARGE samples 		
Terminal Pond Discharge Monitoring POCs		
Radionuclides:	Pu 239, 240	High level of public concern Known carcinogen Known past releases (within the past 8 years) have exceeded RFCA stream standards and action levels This provides reasonable cause to expect future releases in excess of RFCA stream standards and action levels
	U 233, 234, 235, 238	Known renal toxicity Present on Site Past exceedances provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels
	Am 241	Known carcinogen Present on Site Known past exceedances provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels
Real-Time Monitoring of Physical and Indicator Parameters: These parameters provide real-time indicators for a wide variety of regulated contaminants and are also a required component of monitoring for AoIs They require no laboratory analyses and are the Site's most cost effective defensive monitoring	pH	Toxicity to humans and ecology Regulatory concern due to chromic acid incident Real-time monitoring is inexpensive and effective method of detecting acid spills such as (chromic acid or plutonium nitrate) or failure of treatment systems
	Conductivity	Conductivity is an indicator of total dissolved solids, metals, anions, and pH Real-time monitoring of conductivity is an inexpensive indicator of overall water quality
	Turbidity	Turbidity is a general indicator of elevated contaminant levels and may be correlated with Pu
	NO ₃	Past releases near RFCA stream standards and action levels upstream of ponds provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels ITS discharges are often high in nitrate and may challenge RFCA action levels

Table A-27
(continued)

Terminal Pond Discharge Monitoring POCs		
Real-Time Monitoring of Physical and Indicator Parameters (continued)	Flow	Required to detect flow events, evaluate contaminant loads, and plan pond operations and discharges Affects nearly every decision rule and is the most commonly discussed attribute of Site surface waters
Indiana Street Monitoring POCs		
Radionuclides	Pu 239, 240	High level of public concern Known carcinogen Known past releases (within the past 8 years) have exceeded RFCA stream standards and action levels This provides reasonable cause to expect future releases in excess of RFCA stream standards and action levels
	Am 241	Known carcinogen Present on Site Known past exceedances provide reasonable cause to expect future releases in excess of RFCA stream standards and action levels
	Tritium	Tritium is an AoI for the cities due to the past release of tritium (1973)
Real Time Monitoring:	--	Indiana Street is not a point of compliance for the real-time monitoring parameters

Note

Non-POC monitoring specified in Table 2-21 is not reflected in this table, because the parties intend that Indiana Street not be a POC for the parameters

3.0 GROUNDWATER MONITORING

3.1 Introduction

This section of the *Integrated Monitoring Plan* (IMP) describes the groundwater monitoring requirements for Rocky Flats Environmental Technology Site (RFETS or the Site) as outlined in the *Rocky Flats Cleanup Agreement* (RFCA) [Department of Energy (DOE et al), 1996], and how they will be implemented at the Site. All RFETS groundwater monitoring is performed by Site organizations because groundwater contaminant plumes occur within the Site boundaries. Therefore, this IMP covers all groundwater monitoring activities. After a brief history of the monitoring program, this section outlines the goals for groundwater monitoring and describes quality assurance/quality control (QA/QC) components and monitoring components. To evaluate groundwater monitoring needs, one must know the RFCA action levels for groundwater, Site history and areas of contamination, the physical and hydrologic setting of the Site, the effect of contaminated areas on groundwater, and the nature of the groundwater contaminant plumes. This information is presented in Appendices A, B, C, and D to this Groundwater Monitoring section, respectively. Appendix E lists the wells that will be monitored for water quality or for groundwater flow.

3.1.1 Purpose of the Integrated Monitoring Plan for Groundwater

In the past, two plans have been required at the Site to comply with DOE Order 5400.1 (DOE, 1988), a "Groundwater Protection Management Program Plan," and a "Groundwater Monitoring Plan." These two plans have historically been combined into one document, the *Groundwater Protection and Monitoring Program Plan* (GPMPP) (EG&G, 1993a), which defines and describes the groundwater protection and monitoring programs at the Site. In addition, an assessment groundwater monitoring plan was required under the Resource Conservation and Recovery Act (RCRA) for the interim status units on Site. This plan is called the *Final Groundwater Assessment Plan* (GWAP) (DOE, 1993). Other monitoring plans have been developed to address groundwater monitoring requirements as outgrowths of various Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Interim Measure/Interim Remedial Action (IM/IRA) decision documents. This portion of the IMP will serve as the Groundwater Monitoring Plan for the Site, and it will replace the requirements found in the group of plans named above. It will also revise the requirements of the routine groundwater monitoring portion of the Industrial Area IM/IRA decision document (DOE, 1994a) and the French Drain IM/IRA plan (DOE, 1992a).

3.1.2 Brief History of Groundwater Monitoring Activities

The historic growth of the groundwater monitoring network at the Site reflects the increasing DOE, regulatory, and public emphasis on identifying areas of groundwater contamination and preventing contaminant releases to the environment. The first three monitoring wells were installed in 1954 in the Solar Ponds area. A total of 1,055 wells and piezometers were installed at

the Site from 1971 to present Plate 1 shows all the wells that have been installed at the Site since 1974

Wells in the groundwater monitoring network were sampled annually until 1974, twice a year until 1980, and three times a year during 1981 From 1982 to 1995, designated monitoring wells were sampled quarterly Beginning in 1995, designated wells were sampled either quarterly or semiannually, depending on regulatory requirements The wells to be sampled are determined by the types of wells (e g , RCRA), and the areas being monitored Currently, wells are sampled on a semiannual basis The groundwater monitoring program has supported the following compliance programs at the Site

- RCRA programs,
- CERCLA programs,
- The Background Groundwater Characterization Program (completed in 1993),
- The Boundary Well Monitoring Program,
- Groundwater Protection (DOE Order 5400 1),
- French Drain IM/IRA Performance Monitoring Program,
- Industrial Area IM/IRA Monitoring Program,
- New Sanitary Landfill Permit Monitoring Program, and
- Special activities that support hydrogeologic projects, including aquifer testing and hydrogeological characterization

Groundwater has been monitored for radionuclides since the first wells were installed in 1954, other chemical analytes were added in 1974, 1979, 1981, 1985, and 1994 Beginning in 1985, the wells were sampled and analyzed for volatile organic compounds (VOCs), metals, and major anions Limited analyses for pesticides have also been performed Results of groundwater analyses from 1986 to present are compiled in the Site Soil and Water Database (SWD)

In 1993, the large number of wells that were being monitored as an outgrowth of the various remedial investigations at the Site prompted the Well Evaluation Project The *Well Evaluation Report* (WER) (EG&G, 1994c) reduced the monitoring network from 460 wells to 350 wells, but retained those wells in or near contaminant plumes

In 1995, the Well Evaluation Project updated plume maps and again evaluated the monitoring network On the basis of new plume configurations, the number of wells monitored was reduced from 350 wells to 150 wells, and the sample frequency and analyte list were amended

3.1.3 Current Status of the Groundwater Program

In July 1996, the RFCA was approved (DOE, 1996). RFCA replaces the Interagency Agreement (IAG) as the environmental cleanup agreement for the Site. RFCA outlines the goals, objectives, and strategies that will lead to the Site cleanup and closure mission objectives. Supporting activities will reduce, eliminate, or mitigate existing environmental liabilities while maintaining the Site in a safe condition. The Action Levels and Standards Framework (ALF) portion of RFCA contains specific requirements for monitoring and reporting, and it sets action levels for contaminant concentrations in groundwater and in other media (see Appendix B to this section). The IMP is required under RFCA to further define the monitoring programs for the Site.

Defining the groundwater monitoring involved reevaluating the monitoring system to ensure that it was protective of the environment, compliant with all applicable regulations and agreements, and aligned with the new Site mission. A data quality objective (DQO) process was used to determine the function of each well in the network and the decisions supported by information from each well. The DOE, Rocky Flats Field Office (DOE, RFFO), the Colorado Department of Public Health and Environment (CDPHE), and the U.S. Environmental Protection Agency (EPA) stakeholders were directly involved in all decisions about the monitoring network. Results of this evaluation are presented starting in Section 3.2.

3.1.4 Groundwater Interactions with Surface Water

There is considerable interchange between surface water and groundwater at Rocky Flats. Interchange occurs along stream channels, ponds, ditches, and lakes by way of natural hillside and channel seepage and artificial flow control structures, such as foundation drains and dams, that interrupt the natural flow of water. Streams nearest to the Industrial Area are more likely to be contaminated by groundwater discharges and, thus, have traditionally been the focus of most groundwater monitoring.

As shown in Figure 3-1, three ephemeral streams drain the Site. The streams are Rock Creek, Walnut Creek (consisting of three tributaries, "No Name Gulch," Walnut Creek, and South Walnut Creek), and Woman Creek. Groundwater is discharged from the Rocky Flats Alluvium and other surficial deposits through surface seeps and subsurface flow that, in turn, recharge stream flow and the stream valley groundwater system. Segments of streams have been shown to either gain or lose water as groundwater is discharged to or stream water is discharged from the stream channel. Gaining reaches of streams are more likely to be contaminated by groundwater discharges.

3 1.5 General Strategy for Groundwater Plume Management and Remediation

The existence of groundwater contaminant plumes (e g , volatile organic, radionuclide, nitrate) at RFETS has been well documented The *Groundwater Conceptual Plan for the Rocky Flats Environmental Technology Site* (RMRS, 1996) presented a summary of the known information on individual groundwater plumes and possible remedial actions The plume management template below outlines the process for decision making for the management and remediation of plumes at the Site This template serves as a unifying policy for plume management and decision making for groundwater plumes under the IMP and aids in the integration of groundwater functions at the Site

The plume management strategy for RFETS will consist of the following components

- Phase 1 Detection Monitoring

The IMP gives DQOs that establish the methods of detection monitoring in groundwater and the actions that will follow The detection of groundwater contamination that could impact surface water at RFETS will be supported through the current water monitoring programs at RFETS as well as through historic data from past investigations and information on past contaminant spills The surface and groundwater monitoring programs have been established to detect the migration of contaminants in water on Site that could have the potential to move off Site The monitoring programs are dynamic and may be changed to accommodate new insights into contaminant migration The Soil Water Database and the *Final Historic Release Report for the Rocky Flats Plant* (HRR) (DOE, 1992b) are the main repositories for information on groundwater contamination, and both are updated on a regular basis with new data The Quarterly RFCA Groundwater Reports present data generated from the groundwater monitoring under the IMP Exceedances of action levels are also identified and discussed in these reports

- Phase 2 Plume Evaluation

Plume evaluations to determine the potential for groundwater contamination to impact surface water are triggered by reportable exceedances of action levels as defined in the IMP and as reported in the Quarterly RFCA Groundwater Report As stipulated in the ALF, the evaluation is predicated on the confirmatory sampling that follows an exceedance of groundwater action levels The evaluation phase initiates a DQO assessment to determine the data needed to evaluate the nature of groundwater contamination to surface water The following are possible components of an evaluation of surface water impact as determined by plume specific DQOs

- Source identification and contaminants of concern,
- Plume extent through determination of pathway linear and areal extents by subsurface correlation of saturated thickness and permeable lithologies,
- Recharge and discharge through quantification of water balance, flow velocity, gradient and direction for groundwater,
- Concentration loadings and mass flux of contaminants to surface water, and
- Effects due to seasonal variations, natural attenuation of contaminants or changes in discharge due to construction/removal of containment structures, treatment systems or removal of sources

Decisions with respect to plume evaluations will involve the groundwater working group. Results of the plume evaluations will be used to update the environmental restoration (ER) ranking process under RFCA to ensure that the available budget will be allocated to areas with the highest potential for contamination.

- Phase 3 Alternatives Analysis

If a significant impact to surface water has been established, evaluation findings will be used to establish various options for present and long term management of the contamination. These options may include remedial actions or a long-term monitoring strategy to evaluate whether the nature and extent of contamination will change with time. The decision analysis step may include:

- Evaluation of remedial/management alternatives (per the nine CERCLA evaluation criteria) including the no action alternative,
- Determination of DQOs to support the alternative selected, and
- Consideration of practical implications of each alternative including compatibility with other Site closure activities and potential impact to the ecology and environment.

Alternatives will involve discussion with the groundwater workgroup during key phases of the process. Once an alternative has been selected, a remediation/management project will be developed with its own scope, schedule and budget. The project will result in a decision document which will include the choice of alternatives, public review and an outline of the remedial design/construction and/or monitoring actions that are necessary.

- Phase 4 Remedial Design/Construction

If a remedial action decision has been reached, additional information may be needed to aid in the design and construction of a remedial system. A data quality objective process will be employed to establish the decision and data needs to aid in the construction of the remedial system. The remedial system may consist of a groundwater containment or treatment system, or a source removal action. Components of this step may include:

- Preparation and presentation of design documents and construction workplans,
- Preparation and presentation of additional sampling and analysis plans,
- Determination of performance monitoring requirements, and
- Alternatives will involve discussion with the groundwater workgroup during key phases of the project.

- Phase 5 Remedial Decision Validation

Additional groundwater monitoring may be required to validate the efficacy of a remedial action or the no-action alternative. Performance monitoring will consider both the short term and the long term protection of surface water. A DQO process will be employed to establish a performance monitoring system. Decisions will require involvement of the groundwater workgroup during key phases of the evaluation, and the actions will be implemented through the IMP process. The Quarterly and Annual RFCA Groundwater Reports will track the long term results of the monitoring activities and recommend changes if necessary.

3.2 Groundwater Program Objectives

The objectives of the Site groundwater program are to 1) protect surface water quality, 2) ensure compliance with regulations, 3) minimize the chances of further degradation of the Upper Hydrostratigraphic Unit (UHSU), and 4) support the design and selection of remedial measures and assess the effect of any future remedial actions. Development of the IMP and subsequent updates are the responsibility of the Environmental Restoration Department of Rocky Mountain Remediation Services, L L C (RMRS/ER) under the direction the Kaiser-Hill Company, L L C (Kaiser-Hill) and the DOE, RFFO. RMRS/ER directs and implements the Groundwater Monitoring Program. The Site management structure is shown in Figure 3-2.

3.3 Monitoring Objectives

The Site Groundwater Monitoring Program will be integrated with ongoing activities designed to protect surface water from contamination by groundwater. The Groundwater Monitoring Program will do the following:

- Identify groundwater containing contaminants,
- Identify and control contaminant sources,
- Identify contaminant pathways,
- Monitor contaminant concentrations,
- Monitor remediation and decontamination and decommissioning (D&D) actions,
- Protect groundwater from new sources of contamination, and
- Evaluate the effects of groundwater contaminants on surface water

3.3.1 Identification of Potential Contaminants

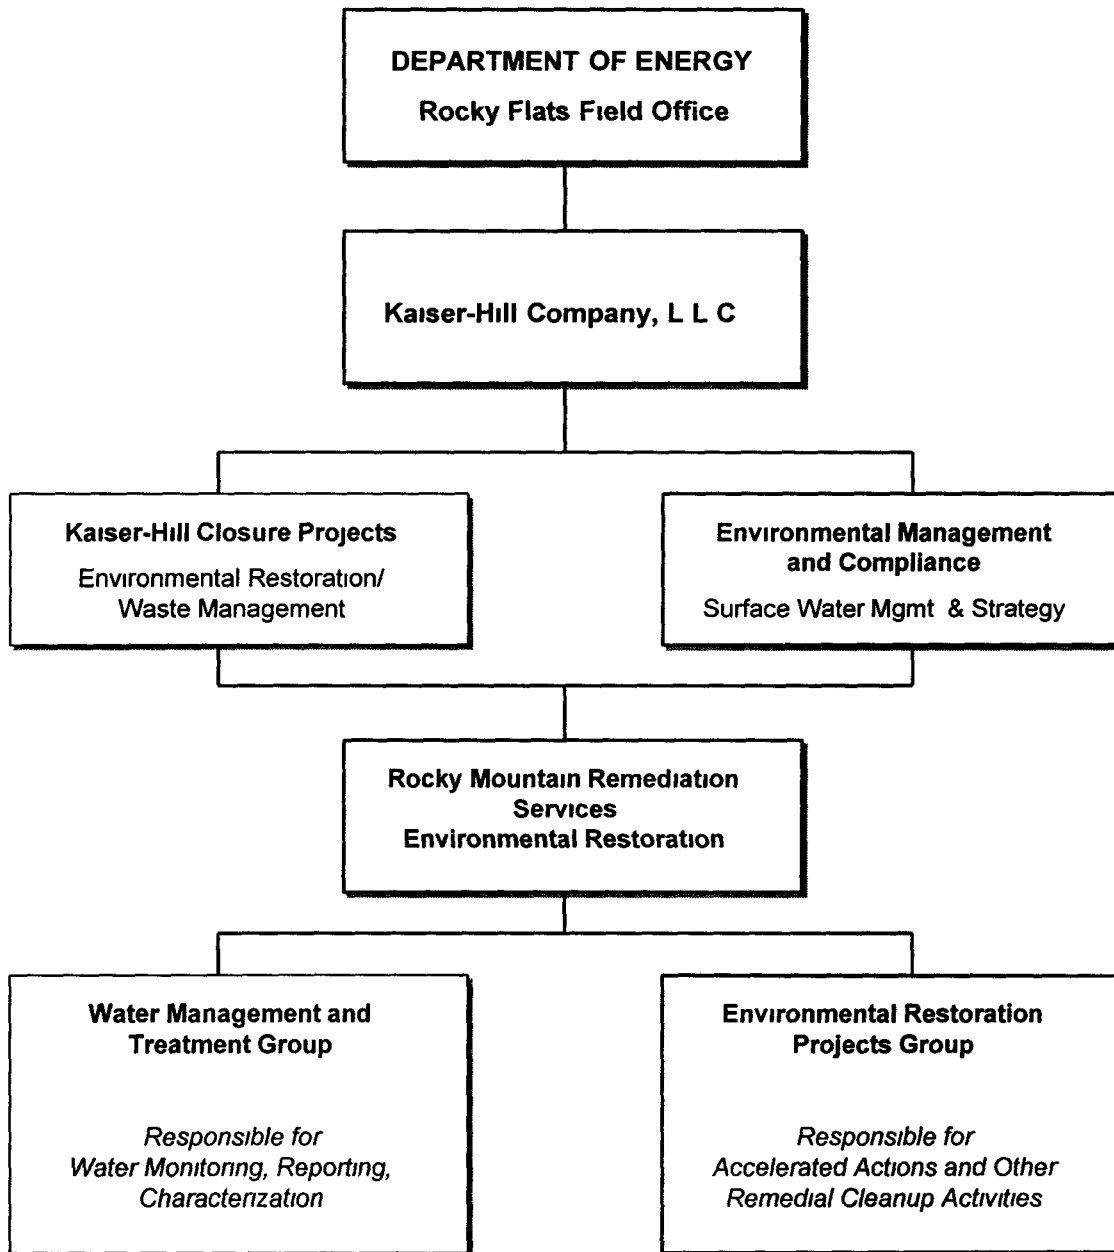

A chemical inventory system has operated since 1986. The current real-time chemical tracking system, which identifies chemicals used on Site that are potential contaminants, has been in operation since 1990. It fulfills RCRA requirements to track the disposition of hazardous chemicals. The Waste Programs Organization at the Site manages this tracking system.

In addition, the HRR (DOE, 1992b) was compiled to originally document spills and other releases of potentially hazardous chemicals at the Site. This report is updated annually and is maintained by the RMRS/ER Department.

3.3.2 Identification and Control of Contaminant Sources

Site area sources contaminated with hazardous substances are identified as Individual Hazardous Substance Sites (IHSSs) and have been characterized under the Remedial Investigation/Feasibility Study (RI/FS) process. The IHSS ER Ranking Project is required under RFCA to determine the relative risk associated with contaminant sources and assign a priority for remediation. Those IHSSs that have contributed to groundwater contamination have been identified and put into the priority list for remediation. The HRR will document any new sources of contamination and will assign an IHSS number to a significant release.

Figure 3-2
Organizational Responsibilities for Groundwater

3.3.2.1 Current Contaminated Areas

The remedial investigations at Operable Units (OUs) (a grouping of IHSSs) have provided adequate data for determining potential contamination sources for much of the Site. The Industrial Area OU has not been characterized as thoroughly as other OUs, but initial soil screening results helped to characterize sources in this area.

Table A-1 lists the IHSSs at the Site. Information about the effect of contaminated areas on groundwater is described in Appendix D to this section. Table D-1 lists the potential contaminants of concern (PCOC) in groundwater and in other media, based on risk assessment criteria in the OUs that have been characterized. The remedial investigations at OUs, combined with Site-wide groundwater characterization activities, have identified a number of groundwater contaminant plumes that emanate from contaminant sources. These plumes are described in Appendix D to this section. The dominant category of hazardous contaminants in groundwater are VOCs. Where feasible, general plume maps have been developed to show the extent of contamination in UHSU groundwater. Plate 3 shows the composite plumes of VOCs and the Solar Ponds nitrate plume. Analyte suites have been developed for wells that reflect the major contaminants of concern.

In areas where groundwater will be monitored during D&D activities, building-specific potential PCOCs will be developed. The RFCA ALF requires performance monitoring of remedial actions. Analyte suites will be developed for these wells based on knowledge of the contaminants of concern at the remediation site (DOE, 1996). However, a full sample suite will initially be collected for these wells as a check on known PCOCs.

Remediation activities protect groundwater by minimizing further migration of potential contaminants and by cleaning contaminated areas. Data are gathered to identify the extent of contamination and the rate of contaminant migration, and to develop a plan for appropriate remedial actions. Data generated by the Groundwater Monitoring Program support the goals of identifying and remediating existing contaminated areas, detecting new contamination caused by D&D or other activities, and preventing contamination of surface water.

3.3.2.2 Hazardous Waste Management Areas

Hazardous or mixed waste management areas at the Site are generally operated in compliance with the RCRA requirements applicable to each area. These are further described in the *Spill Prevention, Control, and Countermeasures/Best Management Practices (SPCC/BMP) Plan* (EG&G, 1992) and the RCRA Part B Permit. The RCRA waste management functions at the Site are the responsibility of Waste Programs.

3.3.2.3 Storage Tanks

The more than 2,000 storage tanks at the Site include underground storage tanks, production or process waste tanks, chemical feed tanks, and fuel oil tanks. Most production and process waste tanks are considered to have secondary containment because they are located inside buildings or have systems that contain spills. Some of the chemical feed and fuel oil tanks also have spill containment systems; these tanks are considered low risk for spills to the ground and thus unlikely to contaminate groundwater.

Further characterization and spill controls for non-waste storage tanks will be achieved with the implementation of the Tank Management Plan, which was developed as a result of the 1989 chromic acid incident (EG&G, 1990). The tank management project employs formal design, testing, and inspection standards to evaluate tanks and prevent environmental contamination. This Tank Management Plan complies with Title 40 of the *Code of Federal Regulations* (CFR) Parts 280, 281, and 282, where applicable. The Waste Programs Organization at the Site maintains and controls the tanks.

3.3.2.4 Process Waste System

The process waste system comprises process waste lines and valve vaults. Groundwater is protected from these systems by 1) inspection of single-contained lines, which are only in accessible locations, 2) development of secondary-containment systems for lines that are not as accessible, and 3) continuous monitoring of leak detectors.

3.3.2.5 Building Drains

The Drain Identification Study (DIS) at OU8 (DOE, 1994b) identifies all those buildings with floor and footing drains located in areas containing potentially hazardous substances, and characterizes whether they lead to sanitary or process waste treatment facilities. Floor and footing drains are considered potential contaminant pathways since a large spill could enter the drains and be transported to the surface-water control system. Should this happen, the spill would be retained, sampled, treated, and released in compliance with permit conditions. Final completion of all DIS tasks, including corrective actions, was completed in August 1996. The *Technical Memorandum No. 1 Data Compilation, Rocky Flats Plant, 700 area (OU8)* (DOE, 1994b) compiles locations and specifications on foundation drains, storm sewers, and sanitary sewers. This information may help define how the drain systems could affect groundwater and surface water flow and migration.

3.3.2.6 Other Potential Contamination Sources

Underground buildings, building operations, and building sumps are also potential sources of contamination. The effect of these sources on groundwater will be further investigated as part of the RMRS/ER program and integrated with D&D activities.

3 3 3 Identification of Potential Contaminant Pathways

To assess the direction and magnitude of contaminant movement, both natural and manmade groundwater migration pathways must be known. The Site groundwater flow regime is determined from water level measurements at monitoring wells. This information can be used to help estimate recharge and discharge rates, and it can be incorporated into water table maps and groundwater flow models that help predict the path along which contaminants migrate.

3.3.4 Identification of Contaminant Concentrations

Routine chemical analysis of groundwater identifies both the contaminants present and the concentration of contaminants with respect to Site action levels or standards. Background concentrations have been established for most inorganic compounds present in groundwater at the Site. These Site-specific background levels are used to help determine concentrations that are anomalous with respect to natural levels. Increases in contaminant concentrations with time may indicate that contaminants are migrating from sources that could affect surface water.

3 3.5 Monitoring of Remedial Actions

The majority of the Site remedial investigation and characterization activities have been completed. Based on these remedial investigations, some interim remedial actions have already been completed, such as the groundwater treatment systems that have been built at the former OU4 and the former OU1. Performance monitoring of groundwater is required for those remedial activities where groundwater has been impacted.

The Interceptor Trench System (ITS) was installed on the hillside north of the Solar Ponds to decrease groundwater migration towards Walnut Creek and to collect groundwater contaminated with high concentrations of radionuclides and nitrate. The water collected in the ITS is pumped to the Building 374 Treatment Plant for processing. Groundwater is not currently monitored immediately downgradient of the ITS, but the Walnut Creek drainage below the ITS is monitored to detect contaminants that are not collected by the system.

The OU1 French Drain System was installed on the 881 Hillside to collect groundwater migrating towards Woman Creek. In addition, groundwater is intercepted in a collection well located near the French Drain and transferred to the Building 891 Treatment Plant nearby. Water that enters the drain is also pumped to the Building 891 Treatment Plant for processing. Groundwater is monitored downgradient of the French Drain system to detect any leakage of potentially contaminated groundwater toward Woman Creek.

Additional remedial activities are planned, as accelerated actions, to excavate and remove hazardous waste sources and to set up additional treatment systems for groundwater. The ALF addendum to RFCA requires performance monitoring of groundwater affected by remedial

cleanup activities. It is anticipated that performance monitoring decisions will be made on a case-by-case basis but will follow a general decision rule that is described in a later section.

3.3.6 Protection from New Contaminant Sources

Future plans for the Site involve decommissioning of Site production systems, building demolition, and excavation and removal or capping of source areas. The IM/IRA for the Industrial Area (DOE, 1994a) proposed a framework for monitoring the effects of building D&D on air, surface water, and groundwater quality. Groundwater will be monitored before, during, and immediately after any operation that could potentially degrade groundwater quality. This monitoring will determine the Site-specific ambient groundwater conditions and detect any release of contaminants to groundwater. Construction activities are also assessed to ensure that groundwater quality is not compromised. Groundwater protection will be considered in future D&D work plans to supplement existing programs for water collected and contained in the building footing drains, basements, valve vaults, and sumps in the Industrial Area. The goal is to monitor the Industrial Area perimeter and promptly detect any contaminant releases, primarily during D&D activities.

Additional sources of Site groundwater contamination may be identified by evaluating data from the groundwater monitoring network at the Site. Evaluation of these data may identify new areas with elevated contaminant concentrations.

3.3.7 Evaluation of Groundwater Contaminant Impacts on Surface Water

In the event that monitoring shows that a groundwater contaminant plume may reach and impact surface water, evaluations will be made to assess this impact. An activity plan will be prepared to identify the specific DQOs necessary for the proper collection and interpretation of information, such that an impact assessment can be made. Once a determination of impact to surface water has been made, a remedial action priority will be assigned.

3.4 Groundwater Data Quality Objectives

DQOs are qualitative and quantitative statements that specify the type, quality, and quantity of the data required to support decision making. At the programmatic level, DQOs are established to ensure that a project has been logically defined and planned, and that project scope will support the eventual decisions required. At the operational level, quality control objectives (QCOs) are established to ensure that data generated by the project will withstand scientific and legal scrutiny, and that the data will be gathered or developed using procedures appropriate for the intended use of the data.

3.4.1 Programmatic Data Quality Objectives

The DQO process was applied to the Site groundwater program at both a programmatic and decision-specific level. At the programmatic level, the DQO process was used to qualitatively evaluate the overall need for, and purpose of, groundwater monitoring. This effort established that groundwater data are needed to comply with applicable regulations, agreements, permits, and to prevent unacceptable risks to public health and the environment through impacts to surface waters of the state. The information required to satisfy these requirements results from regular sampling of wells and surface locations selected to meet the above criteria. These data will be used to detect and document concentrations above limits established by regulations, agreements, permits, or risk-based analysis, to support planning, implementation, and assessment of removals, remedial actions, and D&D projects, to support modeling and evaluations, and to meet commitments to issue periodic monitoring reports to regulators. Sampling locations and frequency have been negotiated with regulators, locations were chosen to detect migration of known contaminant plumes along pathways and across boundaries. Analytical results need to be of high quality, owing to the many uses of the data — modeling, risk assessment, performance assessment, and compliance. These programmatic statements establish the general need for a groundwater monitoring program and outline program elements that need to be included.

3.4.2 Data Quality Objectives for Program Elements

The second DQO effort developed individual monitoring program decision elements. DQOs were approached on a medium-specific basis, although the goal was to integrate monitoring requirements for all media (e.g., surface water, ecology, air). Groundwater monitoring DQOs were developed for each component of the program and problem statements were established. These problem statements were then refined into a decision statement that specified corrective actions for that problem. Then data were identified and methods of analysis outlined to support the decision. Boundaries and scope are defined to clarify the spatial and temporal focus of the required monitoring information and exclude nonessential aspects of the problem. A decision rule was specified to document how data will be summarized to draw a conclusion upon which a decision will be based.

The groundwater monitoring network was defined with the Site-wide components described below.

- **Plume Definition Wells** Wells that are within known contaminant plumes and are above Tier II Action Levels, but are below the Tier I Action Levels established in the ALF. These wells will be monitored to determine whether concentrations of contaminants are increasing, and, if a Tier I Action Level is exceeded, will be reported as a Tier I exceedance and be prioritized for remedial action.
- **Plume Extent Wells** Wells at the edges of known groundwater contaminant plumes along pathways to surface water. A subset of these wells is listed in the ALF as Tier II Wells. The wells are monitored for increases in concentrations that

would exceed Tier II Action Levels stated in the ALF, and they indicate movement that may result in contamination of surface water

- **Drainage Wells** Monitoring wells located in stream drainages downgradient of contaminant plumes. If contamination reaches these wells, and action levels are exceeded, they fall under the same requirements as plume extent wells
- **Boundary Monitoring Wells** Wells used to monitor the quality of groundwater leaving the eastern Site boundary

In addition to this general groundwater monitoring scheme, specific requirements support regulatory directives. The following special categories are included as groundwater program elements

- **D&D Monitoring Wells** Wells used to monitor releases to groundwater from D&D activities on specific buildings. This requirement is specified in the IM/IRA for the Industrial Area (DOE, 1994a)
- **Performance Monitoring Wells** Wells used to monitor the effect of a remedial treatment or source removal action. Performance monitoring of source remediation is specifically required in the RFCA ALF for groundwater. The French drain performance monitoring wells are included in this category and are specified in the French Drain IM/IRA plan (DOE, 1992a)
- **RCRA Compliance Wells** Wells used in upgradient and downgradient monitoring of RCRA interim status units. This requirement is specified under 6 *Code of Colorado Regulations* (CCR) 1007-3. Wells monitored at the new landfill would be specified under 6 CCR 1007-2. Future retrievable storage facilities would also fall under the RCRA monitoring category

On-Site groundwater has a surface water protection use classification and must be managed to be protective of surface water quality. The ALF lists specific analytes and the associated groundwater action levels. All DQO decisions will reflect the RFCA requirement to support the surface water protection classification. Each component of the groundwater program can be considered a decision element, and decision statements have been created for each component

3.4.2 1 Plume Definition Wells

Problem Statement

Are contaminants within groundwater plumes increasing in concentration with time or reaching Tier I Action Levels with the potential to impact surface water?

Problem Scope

Plume definition wells lie within the currently known groundwater contaminant plumes and are located appropriately to monitor groundwater pathways that could affect surface water. Plume definition wells are designated based on knowledge of existing groundwater contaminant plumes and particle flow models that simulate groundwater pathways. It is possible that some plume definition wells have historically exceeded Tier I Action Levels. For these wells, only new exceedances of Tier I Action Levels involving compounds that have concentrations greater than historic levels will cause the well to be reprioritized for remedial action.

Inputs

- RFCA Tier I Action Levels,
- Background mean + 2 standard deviations,
- Historic baseline for contaminants,
- Selected analyte suites based on historic data (see Appendix E to this section),
- Historic data trends for contaminants,
- Field parameters, and
- Water levels

Boundaries

<i>Spatial</i>	Wells are located in areas known to be contaminated above the Tier II Action Level. Decisions will be made on an individual well basis.
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually.

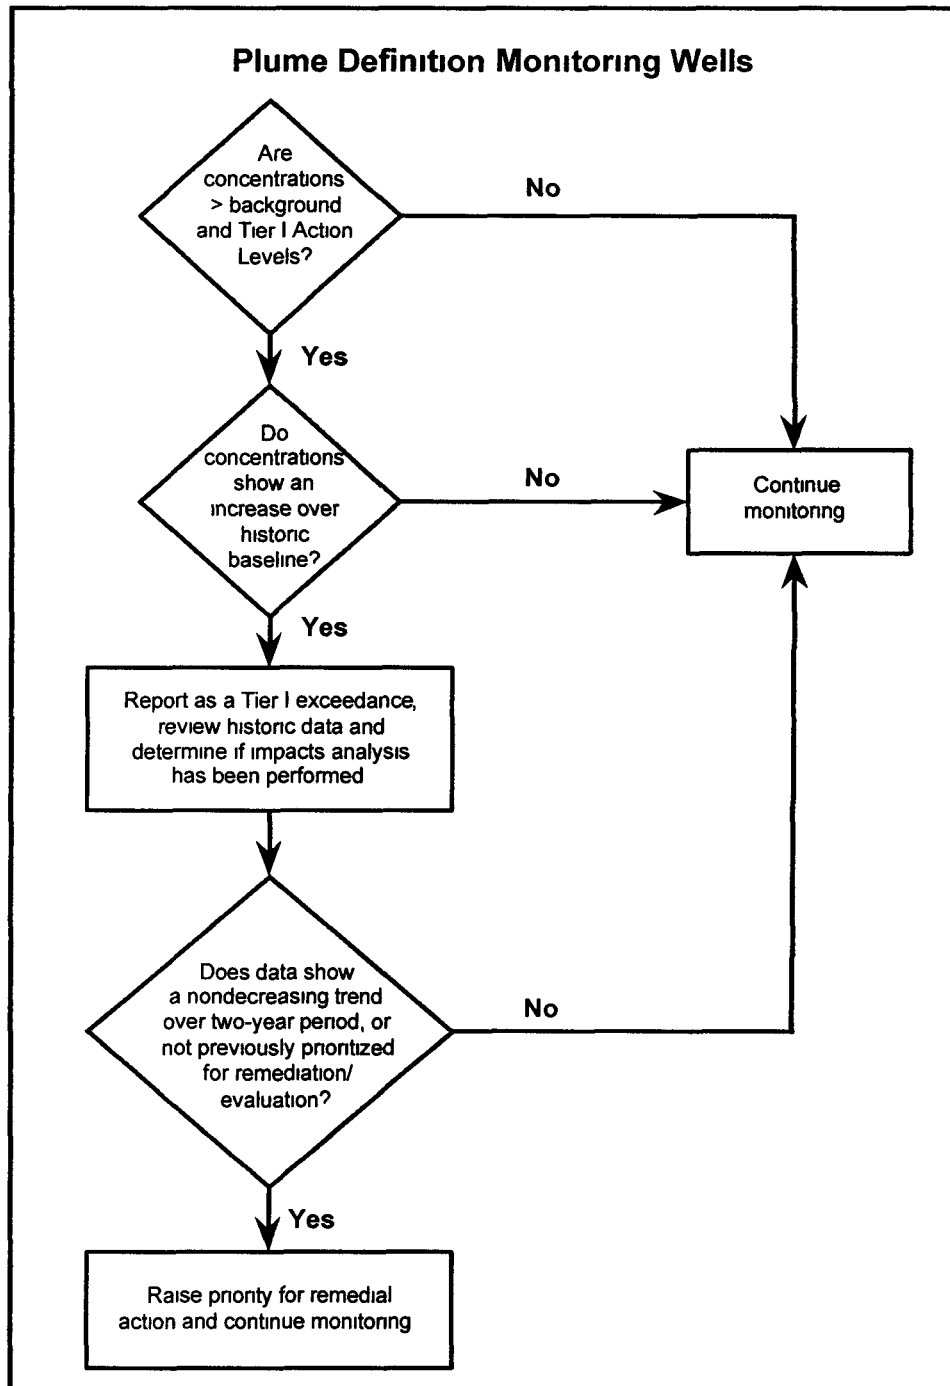

Decision Statement

IF	Measured concentrations in well exceed Tier I Action Levels and background mean +2 standard deviations—
THEN	Report as a Tier I exceedance and review historic data for well to determine if it has been prioritized for remediation/evaluation based on potential impact to surface water.

RFETS Integrated Monitoring Plan

IF	Data show a nondecreasing or increasing trend over a two-year period, or well has not been previously prioritized for remediation—
THEN	Update priority for remediation/evaluation,
ELSE	Continue monitoring

Logic

3.4 2 2 Plume Extent Monitoring Wells

Problem Statement

Have concentrations in wells exceeded Tier II Action Levels?

Problem Scope

Plume extent monitoring is conducted to detect potential impact to surface water from known or suspected groundwater contamination plumes. Some of these wells are specifically listed as Tier II wells in the RFCA ALF for groundwater. If groundwater exceeds Tier II Action Levels, an evaluation is required to determine if remedial or management action is necessary to prevent surface water from exceeding standards. It is possible that some plume extent wells have historically exceeded Tier II Action Levels. For these wells, only new compounds with exceedances of Tier II Action Levels or involving compounds that have concentrations greater than historic levels will be sampled on a monthly basis as required by RFCA.

Inputs

- RFCA Tier II Action Levels,
- Background mean + 2 standard deviations,
- Historic baseline for contaminants,
- Selected analyte suites based on historic data (see Appendix E to this section),
- Historic data trends for contaminants,
- Field parameters, and
- Water levels

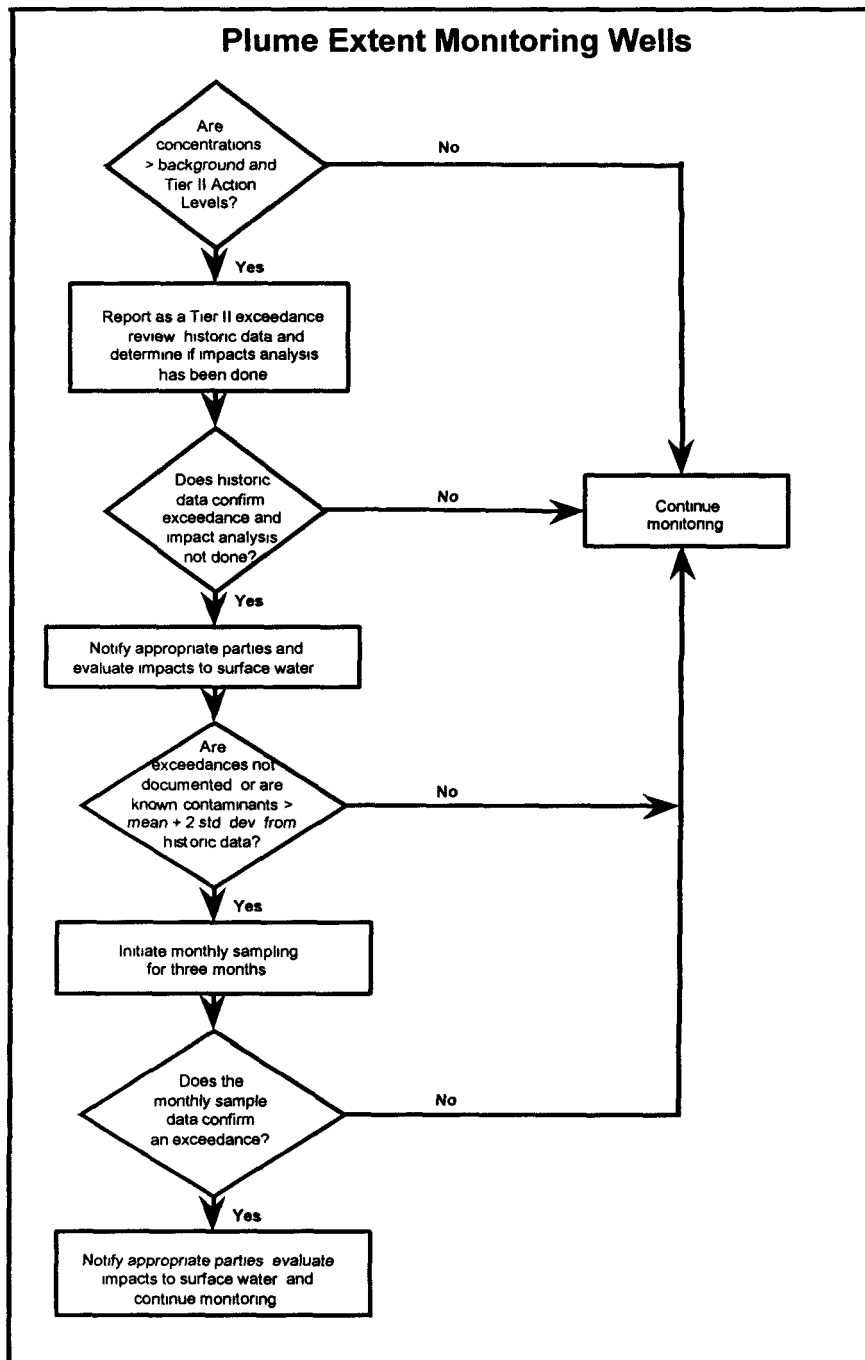

Boundaries

<i>Spatial</i>	Decisions will be made on an individual well basis
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made on an annual basis

Decision Statement

- | | |
|------|--|
| IF | Sample results show detections in a well that exceed Tier II action levels and background mean + 2 standard deviations— |
| THEN | Report as a Tier II exceedance, review historic data for well, and determine if evaluation of impact to surface water has been done |
| IF | Historic data confirm the exceedance and impact evaluation has not been done— |
| THEN | Notify appropriate parties and evaluate impacts to surface water |
| IF | Historic exceedances have not been documented or concentrations for a known contaminant are greater than the mean + 2 standard deviations with respect to the historic data set for that well— |
| THEN | Initiate monthly sampling for three months |
| IF | Monthly sampling confirms the exceedance— |
| THEN | Notify appropriate parties and determine whether a remedial or management action is necessary, |
| ELSE | Continue monitoring |

Logic

3.4.2 3 Drainage Monitoring Wells

Problem Statement

Do contaminants that have reached surface water in groundwater exceed action levels, and are they migrating downgradient in valley fill alluvium?

Problem Scope

In some areas, groundwater contamination from multiple sources has migrated to surface water drainages. Drainage wells monitor groundwater in valley fill alluvium downstream of areas where contaminant plumes may have reached surface water stream drainages. Any contaminants detected in stream drainages are assumed to have affected surface water and to have the potential to migrate off Site. It is possible that some drainage wells have historically exceeded Tier II Action Levels. ~~For these wells,~~ only new compounds with exceedances of Tier II Action Levels or involving compounds that have concentrations greater than historic levels will be sampled on a monthly basis as required by RFCA.

Inputs

- RFCA Tier II Action Levels,
- Background mean + 2 standard deviations,
- Historic baseline for contaminants,
- Selected analyte suites based on historic data (see Appendix E to this section),
- Historic data trends for contaminants,
- Field parameters, and
- Water levels

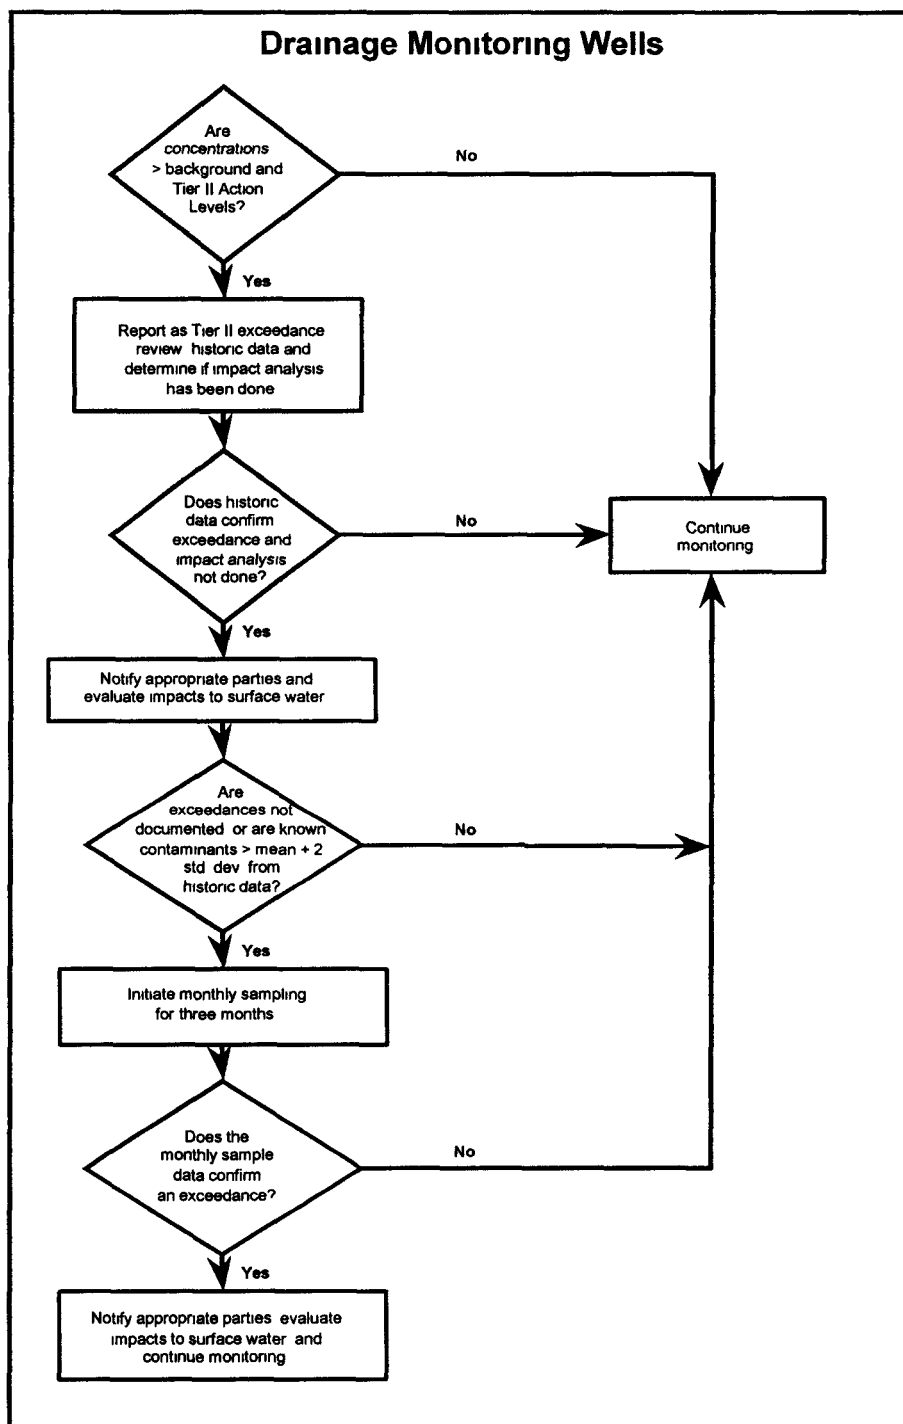

Boundaries

<i>Spatial</i>	Decisions will be made on an individual well basis
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually

Decision Statement

IF	Sample results show detections in a well that exceed Tier II Action Levels and background mean + 2 standard deviations—
THEN	Report as a Tier II exceedance, review historic data for well, and determine if evaluation of impact to surface water has been done
IF	Historic data confirm the exceedance and impact evaluation has not been done—
THEN	Notify appropriate parties and evaluate impacts to surface water
IF	Historic exceedances have not been documented or concentrations for a known contaminant are greater than the mean + 2 standard deviations with respect to the historic data set for that well—
THEN	Initiate monthly sampling for three months
IF	Monthly sampling confirms the exceedance—
THEN	Notify appropriate parties and evaluate impacts to surface water,
ELSE	Continue monitoring

Logic

3 4.2.4 Boundary Monitoring Wells

Problem Statement

Do contaminants in groundwater exceed groundwater action levels, and do they migrate off Site?

Problem Scope

Boundary wells monitor groundwater at the downstream boundary of the Site. Any contaminants detected in boundary wells that are above background and also above action levels are assumed to have impacted surface water and to have migrated off Site. Historically, the Site has monitored wells at the Indiana Street boundary to provide the surrounding cities with added certainty that there are no contaminants in alluvial groundwater leaving the Site. It is possible that some boundary wells historically exceeded Tier II Action Levels. For these wells, only new compounds that exceed Tier II Action Levels or that have concentrations greater than historic levels will be sampled on a monthly basis as required by RFCA.

Inputs

- RFCA Tier II Action Levels,
- Background mean + 2 standard deviations,
- Historic baseline for contaminants,
- Selected analyte suites based on historic data (see Appendix E to this section),
- Historic data trends for contaminants,
- Field parameters, and
- Water levels

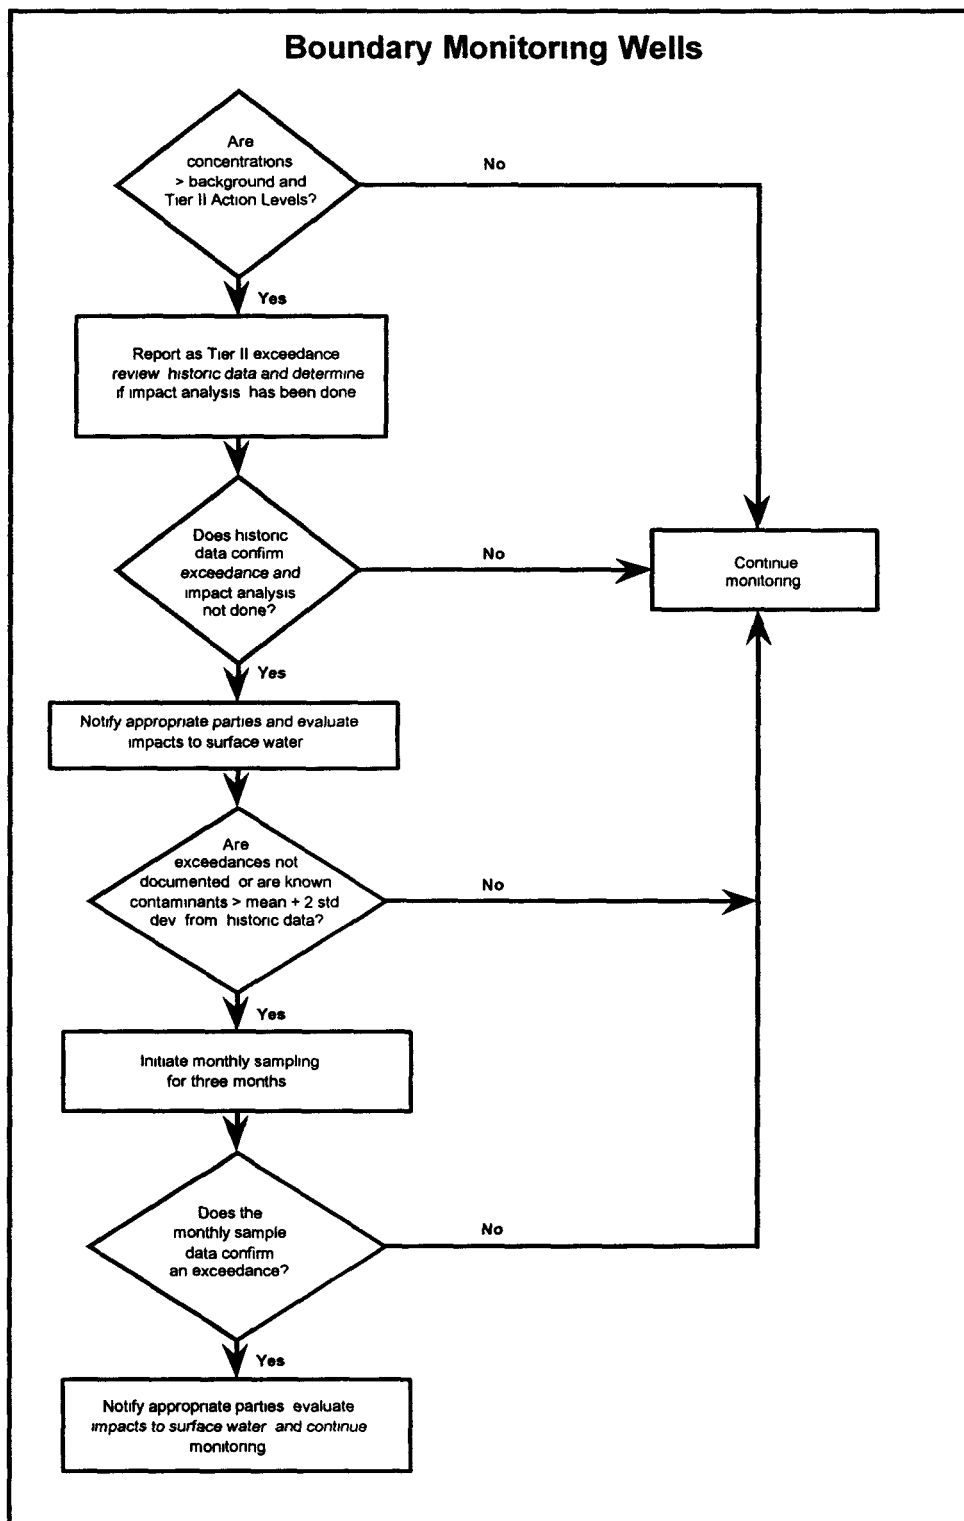

Boundaries

<i>Spatial</i>	Alluvial groundwater in the drainages at the Indiana Street boundary. Decisions will be made on an individual well basis.
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually.

Decision Statement

IF	Sample results show detections in a well that exceed Tier II Action Levels and background mean + 2 standard deviations—
THEN	Report as a Tier II exceedance, review historic data for well, and determine if evaluation of impact to surface water has been done
IF	Historic data confirms the exceedance and impact evaluation has not been done—
THEN	Notify appropriate parties and evaluate impacts to surface water
IF	Historic exceedances have not been documented or concentrations for a known contaminant are greater than the background mean + 2 standard deviations with respect to the historic data set for that well—
THEN	Initiate monthly sampling for three months
IF	Monthly sampling confirms the exceedance—
THEN	Notify appropriate parties and evaluate impacts to surface water,
ELSE	Continue monitoring

Logic

3.4.2.5 Building-Specific D&D Monitoring Wells

Problem Statement

Have building-specific D&D activities degraded groundwater in a way that can impact surface water?

Problem Scope

Building-specific D&D activities involve three major steps: deactivation of building processes, demolition of building structures, and remediation of building foundations and surroundings. The IM/IRA for the Industrial Area outlines monitoring activities to ensure that building-specific D&D actions do not inadvertently degrade surface water through a groundwater transport pathway. The proposed monitoring will provide the data needed to determine if precautions or actions taken during D&D adequately prevent migration of contaminants to groundwater.

Inputs

- Building-specific PCOCs (to be determined),
- Baseline mean + 2 standard deviations,
- Field parameters (to be determined), and
- Water levels

Boundaries

<i>Spatial</i>	Decisions will be made on an individual well basis
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually

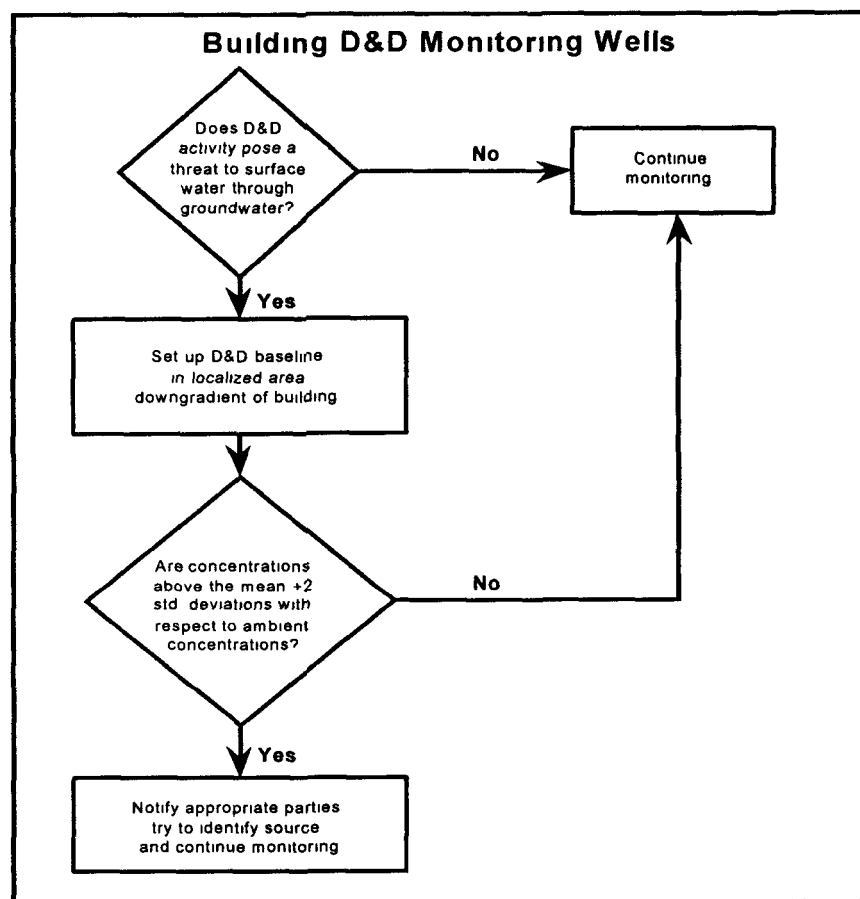

Decision Statement

IF	Existing information from a proposed D&D activity indicates a potential threat to surface water through a groundwater pathway—
THEN	Establish a pre-D&D baseline using wells located upgradient and downgradient of buildings
IF	Exceedances are detected greater than the mean + 2 standard deviations above baseline—

THEN Inform appropriate parties and evaluate the problem,

ELSE Continue monitoring

Logic

3.4.2.6 Performance Monitoring Wells

Problem Statement

Have remedial actions improved or further impacted groundwater?

Problem Scope

Performance monitoring assesses the effectiveness of remedial activities such as contaminant source removals or treatment systems that are installed to clean groundwater plumes. In general, source removals are monitored by comparing current values to values that existed before the remedial action. RFCA requires performance monitoring of all

groundwater and appropriate soil remediation actions. Specific activities will be determined on a case-by-case basis and will be established in decision documents for those projects where it is required. Details will be determined by the groundwater work group in conjunction with project managers and incorporated into the IMP.

Inputs

- Source-specific PCOCs (to be determined),
- Field parameters (to be determined), and
- Water levels

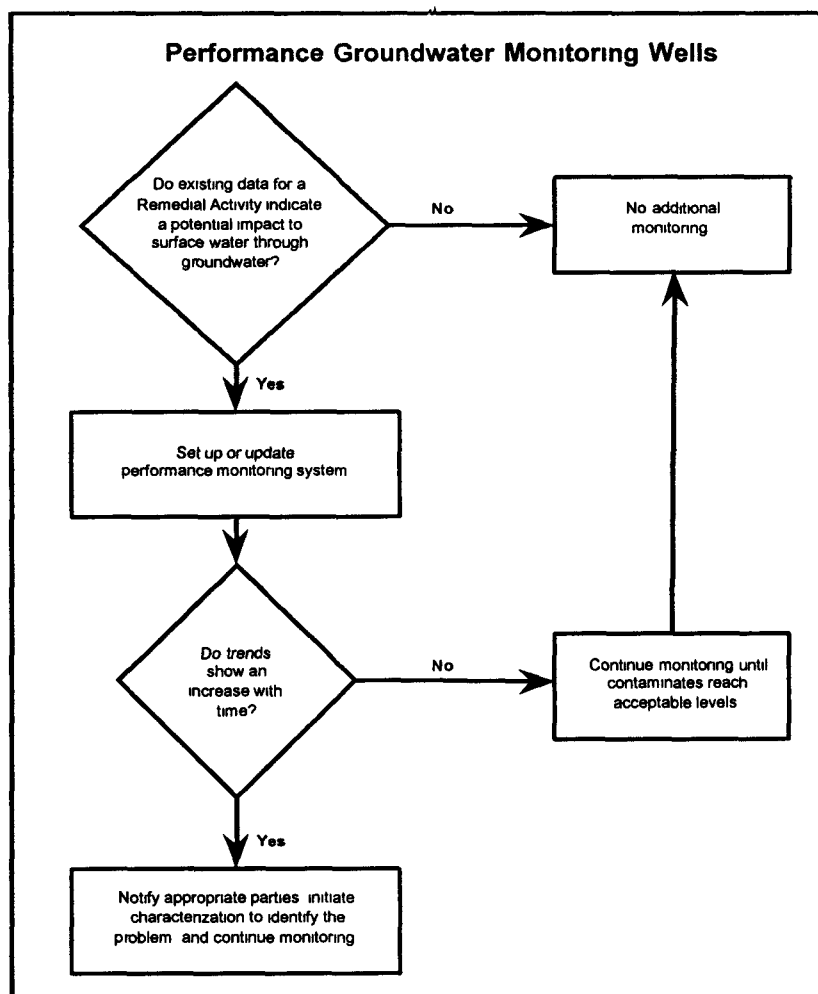

Boundaries

<i>Spatial</i>	Decisions will be made on a well-by-well basis. Wells will be placed downgradient from sources undergoing remediation.
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually.

Decision Statement

IF	Existing data or information from a remedial activity suggest potential impact through groundwater pathways to surface water—
THEN	Establish monitoring points and initiate sample collection.
IF	Monitoring detects that the concentration of contaminants increases with time—
THEN	Inform appropriate parties and initiate evaluation to assess the extent of the problem,
ELSE	Continue monitoring until contaminant levels are reduced to acceptable levels.

Logic

3.4.2.7 RCRA Monitoring Wells

Problem Statement

Have concentrations of contaminants in downgradient monitoring wells exceeded the mean concentrations in upgradient monitoring wells at RCRA units?

Problem Scope

RCRA monitoring is conducted to detect potential excursions of contamination that are below the point of compliance established for RCRA units on Site. RCRA units are considered to be any units that are regulated under 6 CCR 1007-2 solid waste requirements, such as the Existing Landfill and the New Sanitary Landfill, and any future waste repositories. Attachment 10 of the RFCA will be followed in determining points of compliance and alternate concentration limits affecting these units.

Inputs

- Unit-specific PCOCs,
- Field parameters, and
- Water levels

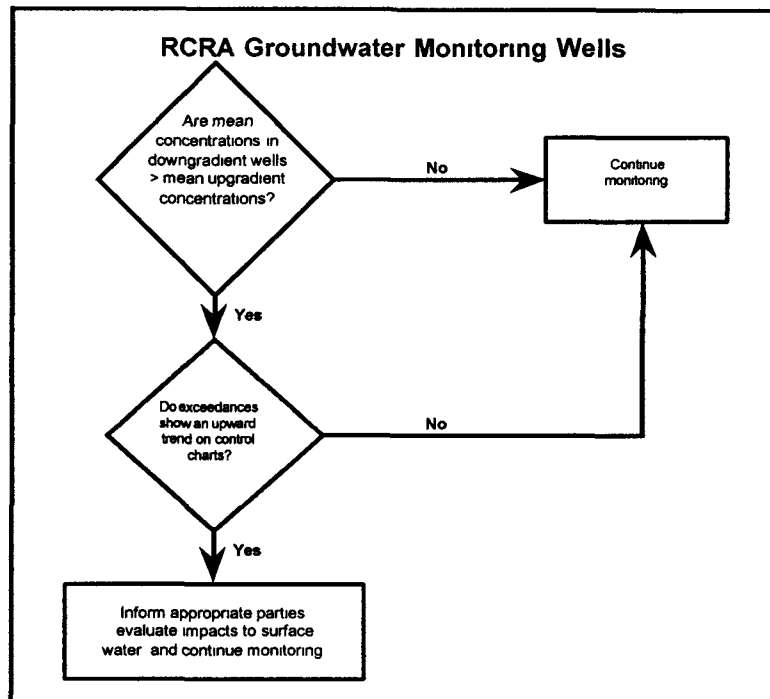

Boundaries

<i>Spatial</i>	Decisions will be made based on pooled results of upgradient wells and on a well head basis in downgradient wells
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually

Decision Statement

IF	Mean concentrations in any downgradient well exceeds the mean concentration in upgradient wells
AND	Concentrations at any downgradient well increase with time—
THEN	Report to appropriate agencies and investigate possible causes,
ELSE	Continue monitoring

Logic

3.4.2.8 Plume Degradation Monitoring Wells

Problem Statement

Do natural processes acting on contaminants in groundwater affect the impact to surface water and therefore influence the priority and method of remediation?

Problem Scope

The natural attenuation of contaminants in groundwater may be a significant factor influencing the nature and extent of contaminant migration. Plumes (and their potential sources) that have been evaluated under the IMP evaluation criteria and show evidence of natural attenuation may need additional characterization or monitoring to establish attenuation characteristics. Degradation monitoring would involve the placement and sampling of wells for use in decision making with respect to the methodology of source and plume remediation and will aid in assessing the priority for remediation.

Inputs

- Concentration and speciation of project specific contaminants in the source groundwater with respect to time,

- Concentration and speciation of project specific contaminants in downgradient groundwater with respect to time,
- Concentration and speciation of background water quality in upgradient groundwater with respect to time,
- Water levels to establish gradient and saturated thickness,
- Project-specific field parameters,
- Trend analysis, and
- Mass flow rate analysis

Boundaries

<i>Spatial</i>	Wells are located in areas thought to be contaminated from a specific source or upgradient to distinguish contamination from other sources
<i>Temporal</i>	Data will be reviewed annually to determine if sufficient data have been collected to support remedial decision making Upon collection of sufficient data an evaluation will be performed to establish inputs to the remedial conceptual model

Decision Statement

IF	Data evaluation concludes that sufficient data have been collected to characterize the nature and extent of the contaminant plume
AND	Evaluation concludes that natural processes have decreased potential contaminant impact to surface water—
THEN	Determine course of action using decision analysis phase in IMP plume management template to reevaluate the priority and methodology for remediation and discontinue monitoring,
ELSE	Reestablish sufficient data needs and re-scope monitoring activities <ul style="list-style-type: none">• General Strategy for Groundwater Plume Management and Remediation<ul style="list-style-type: none">— The existence of groundwater contaminant plumes at RFETS has been well documented <i>The Groundwater Conceptual Plan</i> for the Rocky Flats Technology Site

(Kaiser-Hill, 1996) presented a summary of the known information on individual groundwater plumes and possible remedial actions. This section will outline the general strategy and approach to plume management and decision making for groundwater plumes and show the integration of groundwater functions at the Site.

- The plume management strategy for RFETS will consist of the following components

Detection

The detection of groundwater contamination that could impact surface water at RFETS will be supported through the current water monitoring programs at RFETS as well as through historic data from past investigations and information on past contaminant spills. The surface and groundwater monitoring programs have been established to detect the migration of contaminants in water that could move off Site. The monitoring programs are dynamic and may be changed to accommodate new insights into contaminant migration. The maintenance of historic data in the Soil Water Database and the HRR (DOE, 1992b) help provide information on potential groundwater contamination problems.

The IMP gives DQOs that establish the methods of detection and the actions that will follow.

Evaluation

Many of the DQO decisions for groundwater monitoring require that an evaluation be performed to assess impacts to surface water caused by potential groundwater contamination. In many cases, the evaluation is predicated on the confirmatory sampling that follows an exceedance of groundwater action levels. If follow up sampling confirms an exceedance, or if historic data have indicated an impact to surface water that has not been evaluated, an evaluation will be performed. In general, the evaluation phase will spawn a focused data quality objective which will determine the type of data that will need to be collected and the methodology for determining the nature and extent of contamination and its impact on surface water. The following are possible components of an evaluation of surface water impact:

- Definition of extent of contaminants through additional sampling of soil, groundwater, surface water or seeps,
- Definition of areal extent of the contaminant pathway through additional well/borehole installations,

- Establishment of discharge, flow velocity and direction for groundwater and/or surface water,
- Determination of concentration loadings and mass flux of contaminants to the stream, and
- Estimation of impacts due to seasonal variations, discharges, or removal of groundwater collection systems

It is understood that each evaluation will have a unique DQO that will consider such factors as relative impact, priority, and risk to the public. This approach will ensure that the available budget will be allocated to areas with the highest potential for contamination. Once a significant impact to surface water has been established, the findings will be used to establish or update priorities for remediation. At that point, the scope will be promulgated as an accelerated action, Proposed Action Memorandum (PAM), or an IM/IRA. The ALF section in RFCA that deals with Tier II wells requires modeling of impacts to surface water through mass balancing and flux calculations, where action levels have been exceeded. It is assumed that these predictive components of the evaluation will be weighed against actual field data in setting the priority for remediation.

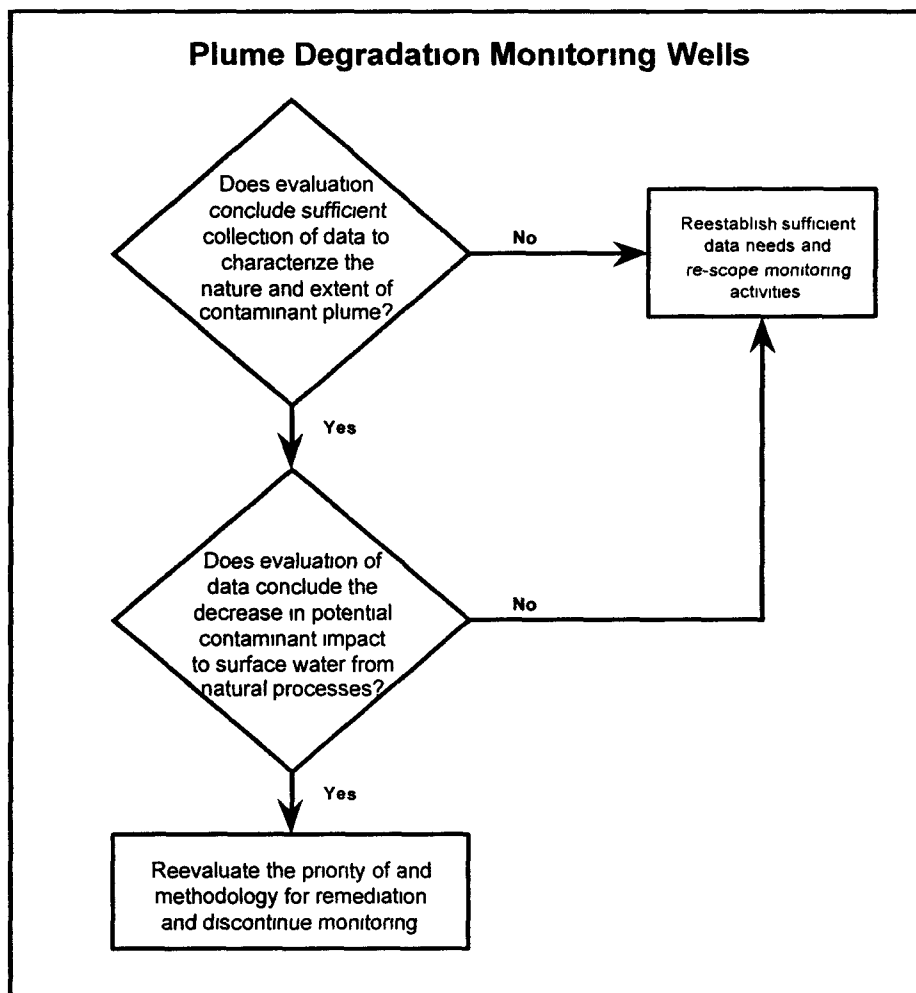

Remedial Decisions

Once impact to surface water has been quantified, and the need for a remedial decision has been determined, the project scope will be promulgated as an accelerated action, PAM, or an IM/IRA. An alternatives analysis will be used to assess the remediation options. This analysis will consider such factors as risk reduction, remediation method, impact on the ecology, cost and performance. Once the remedial decisions have been reached, additional information may be needed to aid the design and construction of a remedial system. A DQO process will be employed to establish the data that need to be collected to aid in the construction of the remedial system. The remedial system may consist of a groundwater treatment system or source removal action. The decision alternatives analysis may propose that no remedial action be performed due to physical or technological impracticality, or adverse impact to the environment.

Remedial Decision Validation

Additional groundwater monitoring may be required to validate the efficacy of a remedial action in reducing the risk of surface water impact. A DQO process will be employed to establish a performance monitoring system that will be maintained during and/or after remedial actions.

Logic

3.4.3 Data Quality Objectives for Monitoring Groundwater Flow

Groundwater quantity and the magnitude and direction of groundwater flow are necessary to assess the effects of Site operations on surface water quality and to design effective remedial actions (if such are needed). Compiling water level information from wells supports the following analyses:

- Assessment of the impact of contaminant plumes on surface water quality through the creation of potentiometric surfaces from which horizontal hydraulic gradient and flow path can be derived,
- Development of groundwater flow and transport models to assess the effect of groundwater contamination on surface water in the event that an action level is exceeded,

- Evaluation of impacts to downgradient habitat and endangered species caused by changes to groundwater quantity and associated fluvial systems as a result of Site remediation activities, and
- Estimation of direction and rate of plume migration and the volumes of contaminated groundwater for use in treatment feasibility scenarios

3.4 3 1 Site-Wide Flow Monitoring

Problem Statement

Do Site remediation activities that adversely affect the quantity, velocity, and direction of Site-wide groundwater flow also adversely affect downgradient habitats or surface water quality and quantity?

Problem Scope

The three flow-monitoring components described below will provide groundwater flow information on a well-by-well basis. To fully evaluate the Site regional groundwater flow regime, monitoring must be spatially distributed to define a potentiometric surface so that maps of this surface can be produced. These potentiometric surface maps can then be used to determine groundwater volume and the velocity and direction of groundwater flow. Water level will be measured more frequently on the perimeter of the Industrial Area where flow information is critical. Wells in areas where groundwater flow is believed to be relatively slow will be monitored at least semiannually. This semiannual flow data will be collected during high recharge and low recharge periods of the year (generally spring and fall).

Inputs

- Water level measurements,
- Frequency of action level sampling,
- Historic water level data, and
- Meteorological data

Boundaries

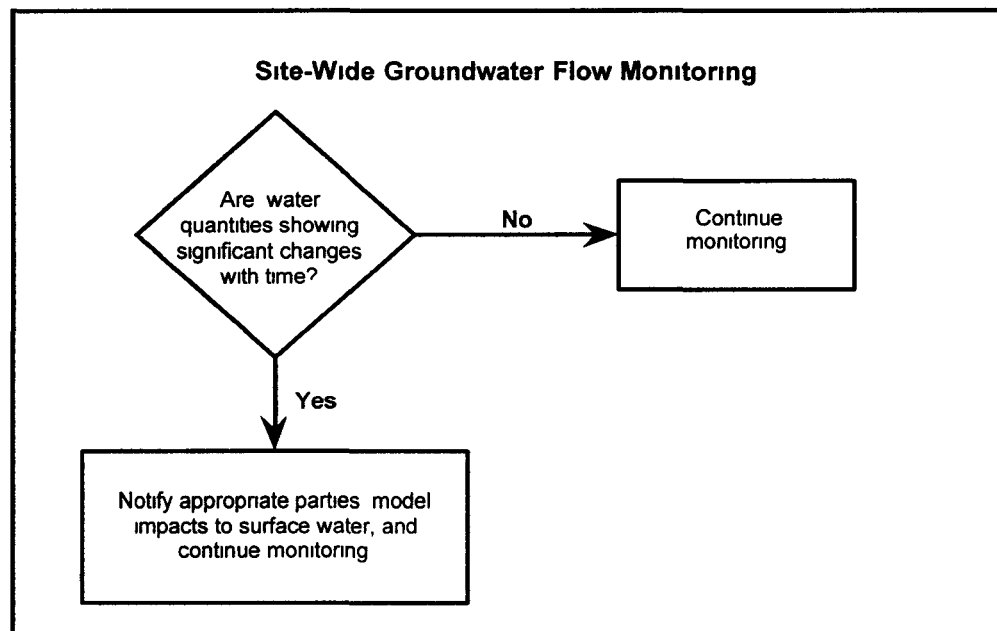

Spatial Decisions will be made on a regional basis

Temporal Data will be reviewed annually and decisions will be made on an annual basis

Decision Statement

IF	Groundwater elevations show significant changes in an area with time—
THEN	Notify appropriate parties and evaluate impacts to surface water quality and quantity,
ELSE	Continue taking measurements

Logic

The Site-wide groundwater flow monitoring program has three components. Each component provides information that supports the programmatic goals. The three components are as follows:

- Water Quality Flow Monitoring, which supports interpretation of water quality data in determining impacts to surface water
- Industrial Area Flow Monitoring, which supports interpretation of changes to the groundwater flow regime leaving the Industrial Area to surface water resulting from remediation activities
- Background Flow Monitoring, which supports interpretation of changes in the contribution of groundwater to surface water resulting from Site remediation activities by monitoring natural and off-Site impacts

3.4.3.2 Water Quality Flow Monitoring

Problem Statement

Do changes in the water level and gradient of groundwater affect surface water quality and flow regime?

Problem Scope

The alluvial water table responds to seasonal and event-related changes in recharge. Interpretations of the fate and transport of contaminants depend on knowledge of the hydraulic gradient and saturated thickness of the aquifer. The frequency of water level measurements should be sufficient to establish useable hydrographs so that the effects of water table fluctuations can be correlated with water quality data. Because water quality sampling frequency is increased when action levels are exceeded, water level frequency should be increased to match the sampling frequency.

Inputs

Water level measurements

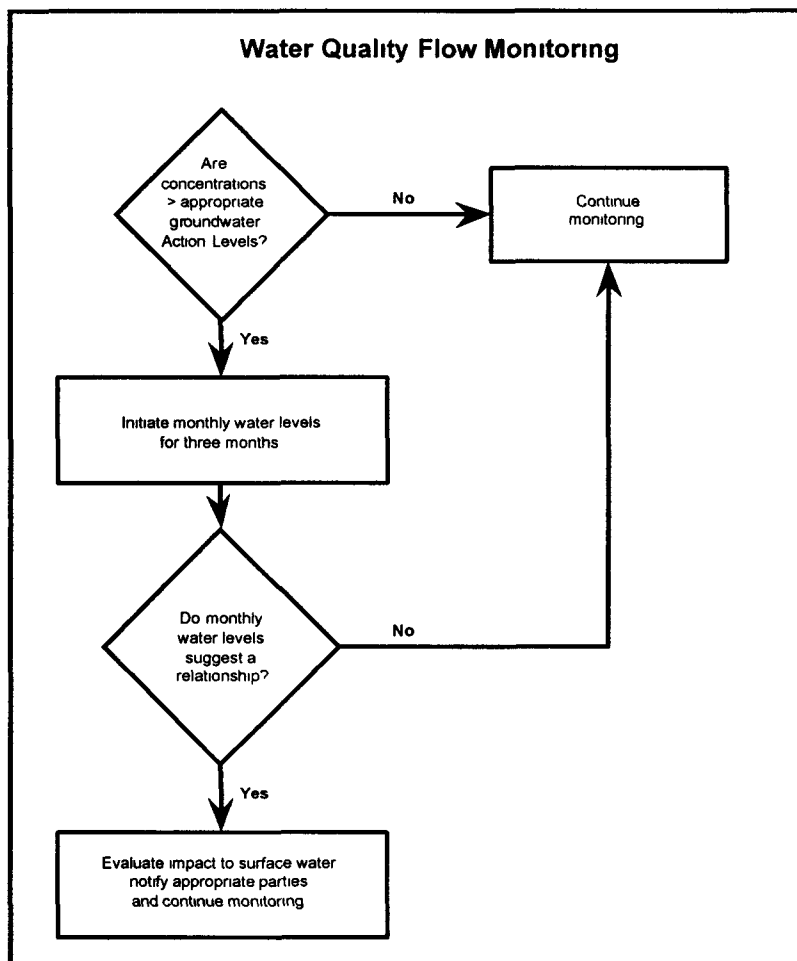

Boundaries

<i>Spatial</i>	Decisions will be made on a well head basis
<i>Temporal</i>	Data will be reviewed quarterly and decisions will be made annually

Decision Statement

IF	Action levels have been exceeded in the well—
THEN	Adjust water level frequency to mirror water quality sampling frequency
AND	Evaluate impacts to determine whether a remedial or management action is necessary,
ELSE	Continue water level measurement at regular frequency

Logic

3.4 3.3 Industrial Area Flow Monitoring

Problem Statement

Do remedial activities affect the groundwater flow regime surrounding the Industrial Area, and what impact to these changes have on surface water quality and quantity?

Problem Scope

The alluvial water table responds to both seasonal and event-related changes in recharge. To understand how remediation activities affect contaminant migration, surface water quality and quantity, and wetlands, the hydraulic gradient and saturated thickness of the aquifer must be known. Because source wells in the Industrial Area are now monitored less frequently, the level of resolution of groundwater flow is too low to predict the effect of Site activities on groundwater migration. The frequency of measurements should be increased to a level sufficient to track the effects of remedial actions in the Industrial Area.

Inputs

- Water level measurements, and
- Historic water level data

Boundaries

Spatial Decisions will be made on a well head basis, but high resolution maps are also needed involving all Industrial Area wells that are monitored

Temporal Data will be reviewed quarterly and decisions will be made annually

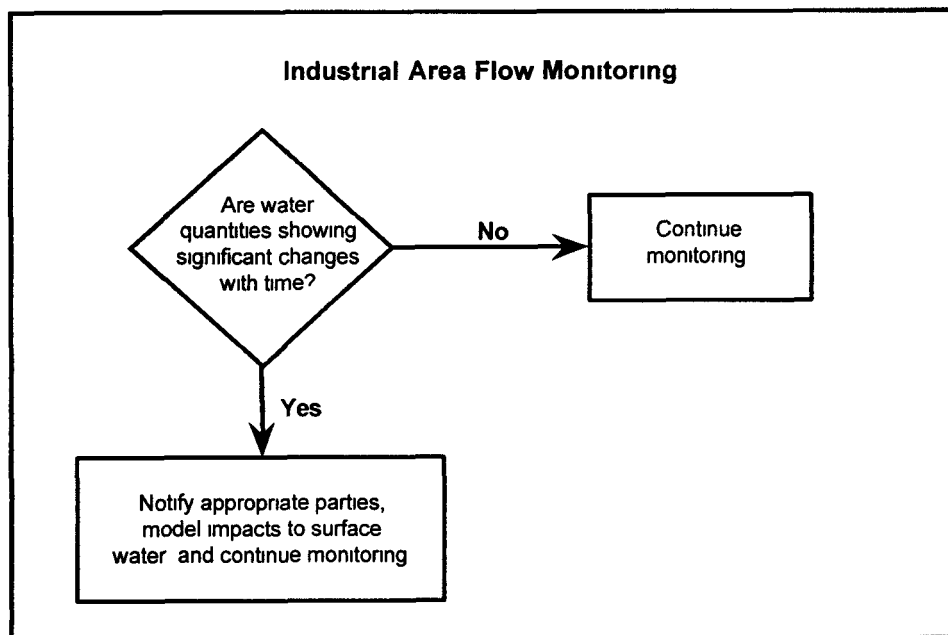

Decision Statement

IF Groundwater levels show significant change with time—

THEN Notify appropriate parties and model effects on surface water quality and quantity using background water level data as appropriate,

ELSE Continue taking measurements

Logic

3 4 3.4 Background Groundwater Flow Monitoring

Problem Statement

Are effects on surface water due to Site activities or natural climatic processes?

Problem Scope

Background quantity, velocity, and direction of groundwater flow must be measured so that the effects of natural climatic or off-Site variations can be filtered out of the evaluations of the effects of Site actions on groundwater

Inputs

- Water level measurements,
- Event monitoring water level measurements, and
- Meteorological data

Boundaries

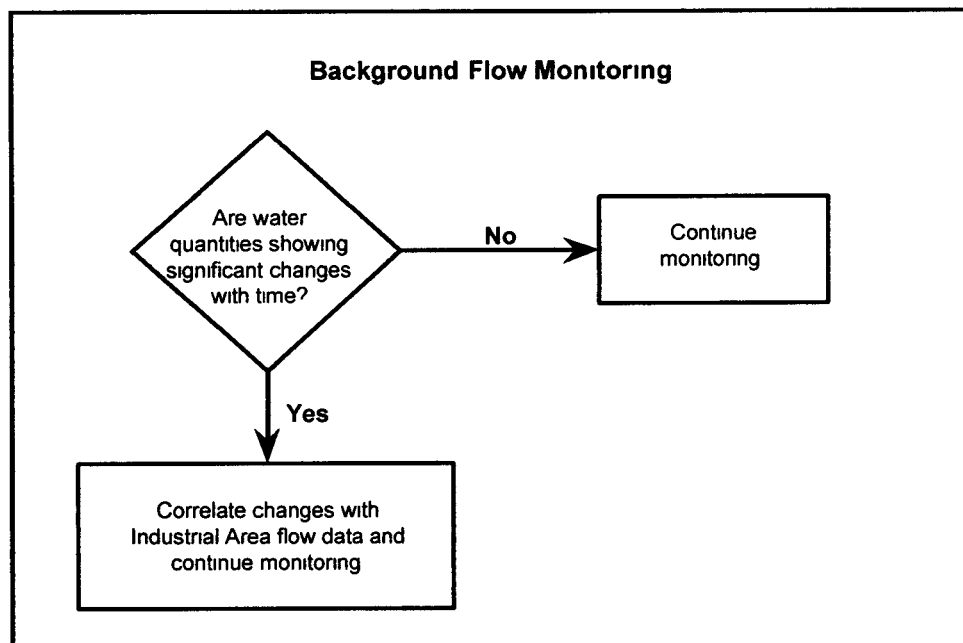

Spatial Decisions will be made on an individual well basis

Temporal Data will be reviewed quarterly and decisions will be made annually

Decision Statement

IF	Site-wide groundwater elevations show significant changes with time that might cause significant impact surface water quantity—
THEN	Evaluate changes in groundwater flow measurements with respect to background flow,
ELSE	Continue monitoring

Logic

3.4.4 Monitoring Frequencies to Meet DQOs

Hydrogeologic interpretation of the sampling media and statistical treatment of existing data sets determine the sample frequency required to meet the DQOs. Sampling frequency should reflect both the velocity that groundwater is moving through the aquifer and professional judgement. Aquifer tests conducted on wells at the Site have provided general estimates of flow velocity in geologic formations. Appendix C to this section gives relative hydraulic conductivities for groundwater in the various geologic units on Site. Groundwater flow in the Rocky Flats Alluvium and colluvium, which are the dominant components of the UHSU, averages 100 to 200 feet per year. Given these rates, a sampling frequency of twice a year would be able to detect a 50- to 100-foot excursion of contaminants. Because most monitoring wells are located 500 to 1,000 feet from major drainages, detection at this frequency would provide adequate time to evaluate and remediate a moving contaminant plume.

The historic variability of groundwater monitoring data can be used to help determine whether a particular sample represents actual changes in the concentration of contaminants. The EPA's Decision Error Feasibility Trials (DEFT) Program can be used to evaluate the expected performance of various sample frequencies based on DQO constraints, assuming that the decision will be based on a comparison of a mean value to an action level. Using two kinds of data (historical data for several wells to obtain estimates of variability, and preliminary limits on decision errors developed during the DQO process) suggest that two to four samples per year adequately determine exceedances of the RFCA action levels. These preliminary investigations, therefore, support the biannual sampling scheme that is proposed.

3.5 Quality Control Objectives for Collection/Evaluation of Groundwater Data

DOE Order 5400 1 *General Environmental Protection Program* (DOE, 1988) requires that a quality assurance (QA) program be developed consistent with DOE Order 5700 6C, *Quality Assurance*. The program must cover all environmental activities and describe the requirements, methods, and responsibilities of environmental management, staff, contractors, and vendors for achieving and ensuring quality. General requirements for the Groundwater Monitoring Program activities are covered under the RMRS Quality Assurance Program Description (QAPD) and associated operating procedures (OPs).

The Site management structure showing organizational responsibilities is illustrated in Figure 3-2. The organization has been structured to maintain quality for the duration of the program. Conformance to the applicable plan, operating procedures, and established requirements will be verified by personnel not directly responsible for performing the work. Issues identified during implementation of the plan will be tracked and closed out through the Site-wide Commitments Management Program (SCMP). Data (operating procedure forms, logbooks, analytical results, and other quality related information as deemed) will be managed in accordance to the Environmental Restoration Management Administrative Procedure RM-06 02, which governs records capture and transmittal, as described in the SWD data management plan. Work-controlling documents are controlled per Operating Procedure ERM Administrative Procedure 2-G01-ER-ADM-06 01 which governs document control.

The RMRS QAPD requires quality control (QC) for the collection and analysis of environmental samples. The major requirements include the following:

- Developing DQOs,
- Collecting and analyzing samples according to approved procedures, and
- Reducing and reporting data in a controlled manner.

DQOs, sampling design and analysis, and ultimate conclusions about groundwater at the Site are based on judgmental sampling (Gilbert, 1987) and consensus decision making (among, for example, RMRS, Kaiser-Hill, DOE, RFFO, CDPHE, and EPA Region VIII). DQOs, conclusions, and decisions are documented through reports, memos, and meeting minutes.

The following documents provide guidance to QA at the Site:

- *The Data Quality Objectives Process* (EPA, 1994)
- *Data Quality Objectives for Remedial Response Activities Development Process* (EPA, 1987)

- *Guidance for Data Usability in Risk Assessment* (EPA, 1990)
- *Rocky Flats Plant Data Management Plan for Environmental Restoration Management Program* (EG&G, 1994d)
- *Evaluation of Environmental Restoration Management Data for Usability in Final Reports* (EG&G, 1994e)

For nonroutine groundwater investigation activities, the types of data, level of detail, and the data quality needed are determined by the DQOs specified for each data collection activity. OU- or IHSS-specific remedial investigations require DQOs with the primary goal of risk assessment and remediation. OU- and IHSS-specific DQOs are established in the work plan or in the QA addenda for that project.

For those data collection activities where project-specific DQOs are not developed, general groundwater DQO guidance is as follows:

- For precision, field duplicates will be collected at a rate of 5% (one in 20 samples), with a relative percent difference not to exceed 30 percent.
- For accuracy, the analytical method and detection or quantitation limits used for each groundwater analyte will be those specified in Analytical Services' *Statement of Work for Analytical Measurement, General Laboratory Requirements* (Kaiser-Hill, 1996), or provided with the instruments in the case of field measurements. Justification for deviation from the project-specific plan must be provided, along with a determination of whether the actual number of samples collected will be adequate for the end use. Laboratory analyses will be independently validated at 25% of the sample population, unless otherwise specified.
- For representativeness, the actual sample types and quantities collected are compared with those planned for the project. Justification for deviation from the project plan must be provided, as must a determination that the actual number of samples collected will be adequate for the end use.
- For completeness, 90% of the groundwater samples and associated QC samples planned for the groundwater monitoring program must be collected.
- Field QC samples will be collected at the rate of 5% (1 in 20 samples) for equipment rinsates and preservation blanks, and will be compared to the real sample using EPA's 5%/10% criterion. Ambient condition blanks are important when groundwater is sampled in areas close to possible sources of volatile organic contamination, such as areas with gasoline engines operating.

3.5.1 Field Data Collection

QC objectives for the collection of field parameters and representative samples of groundwater are established to ensure that data are of sufficient quality to support the decisions identified in the previous section

The QC objectives for field data collection are the following

- Sampled water represents formation water,
- Sampling techniques do not introduce contaminants to samples or wells,
- All sampling techniques are standardized to ensure reproducibility and comparability of results, and
- Water elevations are measured precisely enough to detect minor fluctuations in the water table

3.5.1.1 Representative Samples

All sampling devices are designed to collect representative samples that reflect actual formation conditions. Well productivity is also a factor since some alluvial and bedrock formations at the Site produce so little water that they dewater while purging. Recharge water becomes aerated while cascading along the inner wall of the well casing, which may alter the chemistry of the collected water. Therefore, specific recharge volumes and sampling times have been established that produce samples most closely representing formation conditions.

In addition, micropurging will be used in wells where there is sufficient sample volume to use a dedicated bladder pump. Micropurging collects the sample at a slow enough rate so that turbulence is reduced and limited drawdown is maintained in the well. Use of the dedicated pump also limits the aeration of the sample before it is placed in the sample bottle.

3.5.1.2 Minimization of Contamination During Sampling

Operating procedures are written to ensure that proper techniques are used to collect samples. The groundwater series of OPs describes sampling techniques that minimize operator-induced contamination. All downwell sampling equipment is made of inert materials. Techniques for the use and decontamination of this equipment ensure a high level of sample integrity and minimize the potential for cross-contamination of samples or contamination of any well with foreign materials. One rinse sample is collected for every 20 wells sampled. These analyses are routinely checked to ensure that sample equipment does not cross-contaminate wells.

3.5.1 3 Standardization of Sampling Techniques

Standardization of sampling methodology is ensured by Site standard OPs. These OPs ensure consistency and standardization of sample collection, data entry, field parameter measurements, sample packaging and shipping, and equipment decontamination. Procedures are updated regularly to reflect any changes to the methodology of sample collection, and distribution of procedures is controlled to ensure that work is performed to the most current version of the procedure.

The RMRS/ER OPs (EG&G, 1991a, b, c) that are required to perform the groundwater monitoring tasks have been approved by CDPHE and EPA. Adherence to the directions set forth in these OPs for field operations (FO), groundwater (GW), and geotechnical (GT) activities should produce data that are representative of groundwater quality, comparable from well to well, and reproducible for any given well at the Site.

The collection of groundwater from a new location involves the planning, permitting, and installation of an engineered well. OPs are used at the Site for siting, installing, and sampling wells containing groundwater (EG&G, 1991a, b, c). The applicable OPs are partitioned into three groups (A, B, and C) (Table 3-1) and generally arranged in order of performance. Several of the OPs will be followed more than once (e.g., transmittal of field QA records following completion of a documentable field technical procedure).

All field sampling crews are trained in the techniques described in the OPs, and standardized equipment is used during the sampling events. This uniformity of sampling crews eliminates sampling variability, and samples collected during any quarter can be compared without concern about field inconsistencies.

Adherence to procedures is ensured by both self-assessment audits by project management and formalized audits by the Site health, safety, and quality organizations.

One field duplicate sample is collected for every 20 wells sampled. Field duplicates are used to assess the consistency of sample collection techniques.

3.5.2 Accuracy of Water Level Measurement

Water elevations are taken in accordance with OP GW 1, Water Level Measurements (EG&G, 1991b). Water level measurements are taken by each member of the sampling crew and compared. In addition, total depth of the well is measured to determine whether sediment has collected in the bottom of the well. Wells that contain large amounts of sediment are targeted for redevelopment. Event-related water level measurements may be collected with a continuous data electronic logging device.

3.5.3 Laboratory Analysis

Standardization of laboratory analysis is established through Analytical Services' *Statement of Work for Analytical Measurement, General Laboratory Requirements* which presents the approved analytical methods, holding times, detection limits, and reporting procedures for laboratories performing analytical work (Kaiser-Hill 1996b). Standardization of analytical results allows information generated from different laboratories to be used interchangeably for decision making.

General chemistry samples are typically sent to laboratories approved by the EPA Contract Laboratory Program (CLP). Radiochemistry samples are sent to labs that are licensed to analyze for radionuclides. Groundwater samples are analyzed at prequalified analytical laboratories both on and off the Site. The QA/QC for any non-CLP and non-radiochemistry samples parallels CLP protocol to include continuous equipment calibrations and method blanks for every one in ten samples. The CLP-type analysis is outlined in Section 2.4 of Analytical Services' *Statement of Work for Analytical Measurement, General Laboratory Requirements* (Kaiser-Hill, 1996b). Analytical Services audits laboratories that analyze the Site groundwater samples. The SWD ensures that data are complete and accurate as they are archived into the database by performing automated error checks of the electronic laboratory deliverables. One hundred percent of all analytical data currently undergo a verification review by Analytical Services. At a minimum, 25% of the analytical data produced receives an independent laboratory validation by a subcontractor. This percentage may be reduced in the future to a statistically significant percentage, upon approval of the regulatory agencies.

3.5.4 Data Management

All field data and laboratory analyses performed for groundwater monitoring are maintained in the SWD. This is a relational database that holds all groundwater, surface water, soil, and borehole data collected on Site. All data analysis and reporting are done with data extracted from SWD.

SWD uses Oracle® (registered trademark of Oracle Company) software for data management and retrieval. It compiles water quality data, field parameter data, sample tracking data, and water level data for groundwater, surface water, boreholes, soils, and sediment samples. Field parameter data (sample location, sample date, pH, turbidity, conductivity, and temperature) are included as are groundwater level measurements and chemical information [Chemical Abstracts Service (CAS) registry numbers, analytical results, and detection limits]. Specific procedures for verification of database information received from subcontractors, or input directly into SWD, have been developed and are being implemented. These procedures provide QA documentation, which ensures that all available data have been incorporated and entered or uploaded properly into SWD. Data integrity is maintained with standard OPs and standardized error checking routines used when loading data into SWD. Other procedures are being developed for database system security and software change control.

The field data gathered on Site is entered through the DATACAP field data entry system. This system is a data entry module that is compatible with the SWD database, and can be used in remote field locations by field personnel. Data entered into DATACAP is verified and signed off by the subcontractor before it is delivered to the main SWD database.

Spatial information for groundwater is located in the RMRS/ER geographic information system (GIS) system. This system uses ARC/INFO® (registered trademark of ESRI) software to store and present locational data for well locations, potentiometric surfaces, plume configurations, topographic contours, and Site facilities.

All well and borehole log information is maintained in the Geoscience Group's Logger Database. The Logger Database has graphic logs of all boreholes and wells on Site, and displays well construction details and geologic information. Subsurface geologic correlations are displayed using Earth Vision® (registered trademark of Dynamic Graphics Incorporated) Software.

3.5.5 Groundwater Assessment and Reporting

Part of the data assessment process is to establish that the data are of the requisite precision, accuracy, representativeness, comparability, and completeness (PARCC parameters) to give accurate evaluations for decision making (data usability). Definitions of the PARCC parameters and further information on the establishment of project-specific DQOs are found in the preceding sections.

3.6 Description of the Groundwater Monitoring Program Resulting from the DQO Process

Groundwater monitoring is an essential function of surface water protection at the Site, since the majority of groundwater becomes surface water within the Site boundaries. The overall objective is to identify contaminated groundwater and associated pathways to surface water, and protect those resources from further or potential damage. The goal is to assess the quality and quantity of groundwater resources in the vicinity of the Site to enable proper management of those resources.

Elements of the program include measurement of hazardous constituent concentrations in groundwater, determination of the gradient and direction of groundwater flow, and assessment of the nature and extent of any contaminant plumes in the UHSU within the Site boundaries. The monitoring network is designed to monitor areas of known or suspected groundwater contamination based on composite groundwater plume information and OU-specific source characterization activities. Composite plume maps are presented in Plate 3.

The monitoring well network should undergo constant evaluation to determine the most effective approach to monitoring groundwater at the Site. This evaluation should take into account current regulations and agreements, but, more important, it should integrate new data and technical information on the nature and extent of Site contamination.

The proposed monitoring program comprises the following monitoring components:

- A network of 86 wells sampled on a semiannual basis,
- A network of 12 well and seeps sampled quarterly,
- Monthly measurement of water elevations at 72 wells,
- Quarterly measurement of water elevations at 68 wells,
- Semiannual measurement of water elevations at 100 wells,
- Real-time measurement of water elevations in 25 wells,
- A program plan for updating and proposing changes to the groundwater monitoring program,
- Annual evaluation and reporting to the appropriate regulatory and community agencies,
- Quarterly reporting of groundwater data that exceed action levels,
- A groundwater modeling capability,

- A well control program,
- A well abandonment, replacement, and maintenance program, and
- Other special projects pertinent to groundwater assessment

The groundwater monitoring network at the Site comprises the following seven categories of monitoring wells

- Plume definition,
- Plume extent,
- Drainage,
- Boundary,
- Performance,
- D&D,
- RCRA, and
- Plume degradation

Well categories and wells of the groundwater monitoring network are described in Appendix E of this section (Well List)

3.6.1 Groundwater Monitoring Network

The current DQO evaluation process has prompted a review of the groundwater monitoring program and the determination of specific decisions for each well that is monitored. The general premise is that each well should provide data for a decision or action that is prompted when set criteria are met. At present, groundwater monitoring data are acted on only when they exceed specified action levels for analytes listed in the RFCA ALF document. The list of regulated analytes in RFCA is extensive. Historic data and Site knowledge have been used to determine which contaminants are of major concern in Site groundwater. Table D-1 summarizes the chemicals of concern associated with the various groundwater plumes described in Appendix D of this section. The analyte suites tested for in water from current monitoring wells include the identified chemicals of concern.

The RFCA analyte lists for groundwater use concentration levels that may differ from the Site-specific levels used in the past. Major contaminants of concern were determined after reviews of

historic groundwater data The inorganic and radionuclide data for each well were initially screened against background concentrations using the 99/99 Upper Tolerance Limits reported in the Background Characterization Report (EG&G, 1993b) The data were then screened against the action levels in the ALF and exceedances were noted for each well Table D-1 shows the results of this data screening and was used to determine the analyte suite for the wells in the program The wells were then associated with the IHSS or plume source area where the groundwater contamination originated Areas were delineated based on the known plumes and potential area of influence for those plumes Area-specific monitoring suites were then derived Appendix E to this section contains the analyte suites that will be collected for each well

3.6.2 Sampling and Analysis

The operational groundwater sampling network will contain 89 wells, the majority of which will monitor the extent of various contaminant plumes Appendix E lists the wells in the monitoring program along with their well classification Appendix E also lists the sampling frequency for wells in the program A semiannual schedule of sampling and analysis of water quality in Site wells has been chosen to generate data representative of the various groundwater conditions and to ensure compliance with applicable groundwater regulations The frequency of sampling wells used for other purposes (such as performance monitoring and D&D monitoring) will be derived from compliance documents, agreements, or controlled work plans

A data collection schedule will be adopted for the sampling network This will ensure that samples for any particular well are collected as closely as possible to semiannual intervals The schedule is used as a guide (except as required by specific regulations) and may be modified as needed to account for unplanned changes that occur during the sampling quarter

The following are guidelines for the collection of groundwater samples

- For bailed wells, filtered samples will be collected for metals analyses and uranium isotopes, unfiltered samples will be collected for organics analyses, water quality, and all other radionuclides For micropurged wells, samples will not be filtered
- Well-site field parameters measured are temperature, pH, specific conductance, turbidity, and alkalinity Total dissolved solids will be measured as either a laboratory parameter or a field parameter
- If limited groundwater sample volumes prevent analysis of the entire analyte list, the analyses will be performed in the following order in accordance with RMRS/ER OP GW 6 Groundwater Sampling (EG&G, 1991a)

- 1 CLP Method 524 2 VOCs,
- 2 Semivolatile organic compounds (SVOCs),
- 3 Pesticides/polychlorinated biphenyls (PCBs),
- 4 Nitrate/nitrite, as nitrogen,
- 5 Radiation screen,
- 6 Metals—Target Analyte List (TAL), with cesium, lithium, strontium, tin, molybdenum, and silica,
- 7 Specific metals—list of metals specific to a given well,
- 8 Uranium-233/234, -235, -238,
- 9 Strontium-89/90,
- 10 Plutonium-239/240, americium-241,
- 11 Major anions (chloride, fluoride, sulfate, carbonate/bicarbonate), and
- 12 Tritium

This order in which analyses are to be performed may be altered to fit specific characterization or statistical needs or work plan specifications

3.6.3 Measurement of Groundwater Elevations

Preparation of water elevation maps and hydrographs addresses both a regulatory requirement and a technical need to know groundwater flow directions and gradients accurately. The measurement of groundwater elevations has been designed to produce data that are as representative of current conditions as possible. These water level measurements are collected within 10 working days of the period designated for measurement, so that the data are as temporally related as possible.

Based on the DQO for each activity, Appendix E lists the frequency of water level measurement proposed for the components of the Site-wide Groundwater Flow Monitoring Program.

3.6.4 Groundwater Reporting

Groundwater activities will be reported throughout the life of the Site monitoring program. Reports will be transmitted to EPA and CDPHE as the responsible parties listed in the DQO decision statements in Section 3.4.2, after review and approval by DOE.

225

The following basic reporting vehicles are required for the groundwater program based on the integration of past regulatory requirements with the RFCA ALF

3 6.4.1 Annual Report

An annual assessment of groundwater conditions is required in the DQO decisions in this document, the Industrial Area IM/IRA, and in the regulations governing RCRA interim status units and municipal landfills (6 CCR 1007). Therefore, this report will incorporate the data elements that were historically reported in the RCRA Annual Groundwater Report, Well Evaluation Reports, and IM/IRA reports. This annual report will replace these latter reports and will be the primary compliance report for groundwater monitoring. This integrated report will contain the following elements:

- A general description of the various monitoring program elements, including any new monitoring or sampling activities
- Interpretation of the geochemical data generated from the year's sampling with respect to action levels and trends that may show contaminant movement. Where documented exceedances exist, the report will evaluate the need for further actions and propose those activities.
- Interpretation of the Site groundwater flow-through analysis of water level data collected by use of hydrographs, potentiometric surface maps, and modeling, where appropriate.
- Recommendations for improvements to the monitoring program that may include changes in the well network, analytes collected, and sampling frequency.

In general, reports on potential exceedances for wells will use the following methodology:

Plume Definition Wells

- Data will first be compared with Tier I Action Levels for groundwater. If an action level has been exceeded for any analyte that has an action level, data will then be compared with background values using the mean + 2 standard deviations established in the 1993 Background Characterization Report (EG&G, 1993a).
- If both the action level and background levels have been exceeded for an analyte that has not had consistent historic exceedances, an evaluation will be proposed. Remediation and/or management decisions will be made based on the results of the evaluation.
- If a particular contaminant has been detected consistently above the Tier I Action Level in historic data, then the result will be plotted against historic data set for

that analyte and that well. If the analytical results show an increasing trend in concentration over a two-year period with respect to the historic data set, then an evaluation will be proposed and remedial priority established.

For purposes of data analysis the historic data set is defined as the data generated for a particular well from the years 1991-1995. If a well does not have this data set, or is a newer well, the historic data set will be all data generated for the well until a five-year data set is reached.

Plume Extent, Tier II, Drainage, and Boundary Wells

- Data will be compared with Tier II Action Levels for groundwater. If an action level has been exceeded for an analyte, data will then be compared with background values using the mean + 2 standard deviations, established in the 1993 Background Characterization Report (EG&G, 1993a).
- If both the action level and background level have been exceeded by an analyte that has not had consistent historic exceedances, monthly sampling will be performed per RFCA. An evaluation will be proposed to determine the impact to surface water. Remediation and/or management decisions will be made based on the results of the evaluation.
- If a particular analyte has been detected consistently above the Tier II Action Level and background in historic data, a check will be made to see if an evaluation of impact to surface water has been performed. If no evaluation has been performed, an evaluation will be proposed. If an evaluation has been performed, then future monitoring results will be tested against an historic data set of values for that analyte and that well. If the result is higher than the background mean + 2 standard deviations with respect to the historic data set, then another evaluation will be proposed to assess impacts to surface water.

Building D&D Monitoring Wells

- Performance wells may be existing monitoring wells or special wells installed to detect any unplanned excursion of contaminants during a building D&D activity. Where there is a groundwater concern, a baseline should be established for water quality before D&D activities begin. The baseline should be established one year prior to the D&D action and should be composed of a minimum of four sample events. After the baseline is established, any exceedances above the baseline mean + 2 standard deviations will be reported. Trend plots may be used to track concentrations where exceedances are determined. The results of building specific decisions may also be addressed in the Industrial Area IM/IRA annual report.

Performance Monitoring Wells

- Performance wells may be existing monitoring wells or special wells installed to measure the effectiveness of a source removal or plume treatment system. In each case, it is assumed that the wells that will be used already exceed Tier I or Tier II Action Levels. Therefore, the trend in concentration with time is the best measure of performance. Trend plots will be constructed to track whether contaminant concentrations change with time. A performance monitoring activity may also be described in separate closure documents for that source area.

RCRA Monitoring Wells

- The reporting of monitoring wells used for a permitted RCRA facility are prescribed in the state and federal regulations. Reporting will follow the requirements of these regulations and associated guidance documents. The results of unit-specific monitoring requirements may also be addressed in specific annual reports. An example of this is the annual report for the Existing Landfill.

The annual report will provide the results of monitoring on a calendar year basis. The annual report will be submitted to the DOE at the end of the fiscal year in which the calendar year ended. This date is typically September 30. DOE will review and transmit the report to the regulatory agencies by November 15.

3.6.4.2 RFCA Quarterly Reporting

Quarterly reporting of groundwater analyses is currently required for 1) RCRA interim status units, 2) the boundary wells under the Agreement in Principle, and 3) the French drain monitoring wells under the IM/IRA for the French Drain, and a RFCA ALF document.

The RFCA quarterly report for groundwater will replace all previous quarterly reports and integrate all the various reporting elements into a standardized evaluation, using the action levels as a means of assessing results. The report will summarize the data collected and any exceedances of standards that have occurred using the methods outlined in the previous section. Because semiannual sampling is proposed, the quarterly reports will present only those data that have been analyzed and uploaded into SWD in time for the report. The report for any calendar quarter will be compiled 60 working days after the end of the quarter to allow time for laboratory analysis, data upload, and evaluation. The reports will be issued and presented at the next Quarterly Information Exchange Meeting following the 60-day compilation period. Summary results from the data evaluation will be submitted to DOE, EPA, and CDPHE one week prior to the Quarterly Information Exchange Meeting.

3.6.5 Evaluation of Groundwater Impacts To Surface Water

Many of the DQO decisions for groundwater monitoring require that the effect of potential groundwater contamination on surface water be evaluated. In many cases, when groundwater action levels are exceeded, confirmatory samples will be taken. If analyses of follow-up samples confirm an exceedance, or if historic data indicate an impact to surface water that has not been evaluated, an evaluation will be performed. In general, the evaluation phase will result in a focused data quality objective that will determine two things: the type of data that need to be collected, and the methodology for determining the nature and extent of contamination and its effect on surface water. The Plume Management Template in Section 3.1.5 outlines the role of plume evaluations in the overall Plume Management Strategy.

3.6.6 Groundwater Flow Modeling

Computer modeling of the groundwater system at the Site is a valuable tool for characterizing the groundwater flow regime and determining the fate of potential contaminants introduced into the groundwater system. The primary purpose of groundwater modeling is to integrate geologic, hydrogeologic, and geochemical characterization data into numerical representations of the groundwater system. These models provide predictive capabilities that can be used to analyze and design a groundwater monitoring network, and to evaluate how groundwater affects surface water.

This plan proposes that the current groundwater flow model and supporting software and graphic coverages should be maintained and updated; they are used in problem-solving and tracking how Site closure activities affect the environment. The activity would update and maintain the input grids and coverages for modeling so that real-time simulations can be run when potential impacts to the environment are discovered. Numeric modeling will be used if it is established that the project merits a numeric solution. This will be decided during the DQO development phase of the evaluation.

An annual status report for the maintenance and update of the groundwater flow model, including the results of any modeling performed, will be incorporated into the RFCA Annual Report.

3.6.7 Well Control Program

The Well Control Program is currently a Site Level 1 administrative procedure for new well and piezometer installations (EG&G, 1994a). The procedure is implemented through the RMRS/ER Groundwater Group. The Well Control Program ensures that proper recording and tracking of all well installation activities on Site are done, and serves as a necessary approval process for the installation of wells. The program will support the following activities:

- Assigning well location codes to eliminate misidentification of wells or use of redundant well names

- Maintaining a database with summary well information to be used for evaluation of the functions of new wells, and preparing and obtaining well permits as required by 2 CCR 402-2 regulations. The instructions and form are available in the Environmental Management Department OP GT 6 1994 revision (EG&G, 1991a)
- Maintaining a database of well construction information and geologic log information that must be submitted with the permit applications
- Submitting to the State Engineer's Office permits for wells that are installed or abandoned
- Maintaining the Site geologic core repository for use in correlation of geologic strata and interpretation of hydrogeologic properties
- Through an approval process before well construction, ensuring that wells are installed following applicable procedures and with appropriate knowledge of geologic and Site conditions

3.6.8 Well Abandonment and Replacement

In certain cases, the usefulness of a groundwater monitoring well is exceeded by its potential liability. Such wells should be considered for abandonment or, in certain cases, replacement. Abandoning a well eliminates it from the monitoring network in such a manner that the well will not remain a conduit for groundwater or contaminant migration. Installation and monitoring procedures have been established to minimize the need for abandonments. However, well abandonment is a necessary component of the Groundwater Monitoring Program. Damaged wells must also be abandoned.

This IMP proposes that proper abandonment of wells be required under the following circumstances:

- When the potential for cross-contamination from the well exists,
- When the well is poorly constructed or of unknown construction,
- When the well is in the way of proposed construction or demolition activities, and
- When the well has been damaged

A report describing the results of the Well Abandonment and Replacement Program (WARP), including well installations, abandonments and replacements, will be included as a section in the RFCA Annual Report.

A.1 Site Description

Rocky Flats Environmental Technology Site (RFETS or the Site) is located 16 miles northwest of Denver in Jefferson County, Colorado, and is situated within a 50-mile radius of 2.1 million people. The Site encompasses approximately 6,550 acres of federally-owned land (Figure A-1). Ownership, however, does not include surface and subsurface minerals or water rights. The Site is a U.S. government-owned and contractor-operated facility. Site construction was initiated in 1951 and operations began in 1952 (DOE, 1992).

RFETS was part of the nationwide nuclear weapons research, development, and production complex governed by its original mission. The plant produced metal components for nuclear weapons from plutonium (Pu), uranium (U), beryllium (Be), and stainless steel. Other production activities included chemical recovery and purification of recyclable transuranic radionuclides, metal fabrication and assembly, and related quality control functions. The plant conducted research and development programs in metallurgy, machining, nondestructive testing, coatings, remote engineering, chemistry, and physics. Parts manufactured at the Site were shipped off Site for final assembly.

Major plant structures, including all production buildings, are located within a 400-acre Industrial Area (Figure A-2), with a 6,150-acre Buffer Zone that surrounds the Industrial Area. Industrial activity immediately adjoining the Site includes present and/or prior coal and clay mining, petroleum recovery, natural classified-aggregate quarrying, and fabricated-aggregate mining. Other activities include cattle ranching and wind energy research. Several irrigation ditches intersect the Site, transmitting water for downstream agricultural, industrial, and municipal purposes. Three ephemeral streams drain the Site and flow eastward.

The Site operations have generated solid and liquid nonhazardous, hazardous, radioactive, and mixed (hazardous and radioactive) waste streams. These wastes have been handled and disposed of in a variety of ways. Solid nonhazardous and nonradioactive wastes are disposed of at the Site landfill. Hazardous and mixed radioactive wastes are present on Site and recycled, stored on Site, or shipped off Site for recycling, treatment, or disposal.

A.2 Environmental History

Processing and fabrication of weapons-related components began at the Site in 1952. At that time, environmental protection measures were established that seemed consistent with prudent environmental management. However, some activities resulted in the environmental contamination of portions of the Site. Efforts to document the extent of Site contamination are in progress, in accordance with the Resource Conservation and Recovery Act (RCRA), the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), and the *Rocky Flats Cleanup Agreement* (RFCA) (DOE et al, 1996), a cooperative agreement between the Department of Energy (DOE), the U.S. Environmental Protection Agency (EPA), and Colorado Department of Public Health and Environment (CDPHE). In addition, an Historical Release Report (HRR) (DOE, 1992) has been developed that documents knowledge gained to date about contamination arising from past practices. The HRR is updated annually to document any changes in status for known spills and contaminant sources.

A.2.1 Definition and Description of Contaminated Sites

Section 3004(u) of the RCRA requires that all Solid Waste Management Units (SWMUs) be identified. This became applicable to the Site with the signing of the Compliance Agreement between the State of Colorado and DOE, on July 31, 1986 (State of Colorado, 1986). The exact definition of SWMUs had not been formalized. Therefore, the Site used guidance from the State of Colorado and EPA Region VIII (EPA, 1985). The State of Colorado and EPA required the identification of all areas where releases to the environment may have occurred, including hazardous waste and nonhazardous waste. Also included were single-release areas and locations where long-term management of waste may have occurred.

The SWMUs were initially identified in the *Comprehensive Environmental Assessment and Response Program (CEARP) Phase I Installation Assessment* (DOE, 1985). The SWMUs consisted of inactive waste disposal sites, accidentally contaminated sites, and sites found to pose potential environmental concern due to past or current waste management practices. Inspections were conducted on each site. The first identification of SWMUs [now titled Individual Hazardous Substance Sites (IHSSs)], consistent with the guidance provided by the State of Colorado, was presented as an appendix to the November 1986, RCRA, Part B Permit Application (Rockwell, 1986).

The SWMUs at the Site were renamed as IHSSs in the Interagency Agreement (IAG), which became the compliance document for Site cleanup under RCRA and CERCLA (State of Colorado, 1991). The term IHSS is specific to the Site and is defined in the IAG (Section 3.2.8) as "locations associated with a release or threat of release of hazardous substances which may cause harm to human health and/or the environment."

Once the IHSSs were identified, they were grouped into Operable Units (OUs). The IHSSs were grouped based on cleanup priorities, waste type, and geographic setting into 16 OUs, as defined in the IAG. Under RFCA, the OUs have since been consolidated to eliminate redundant paperwork and to streamline the CERCLA remediation process.

Table A-1 lists IHSSs for each OU. Figure A-3 shows the IHSSs and their locations relative to the original 15 OUs located within the Site. Investigations of off-Site contamination beyond the Site boundary were investigated under OU3, which encloses 38 square miles and is not shown on Figure A-3.

These IHSSs have been investigated according to schedules presented in the IAG (State of Colorado, 1991).

The IHSS list is updated as new IHSSs are identified in the HRR (DOE, 1992). Each IHSS is considered a potential source of environmental contamination and, therefore, a potential source of contamination to groundwater.

C 1 Geology

C.1.1 Introduction

Rocky Flats Environmental Technology Site (RFETS or the Site) is situated approximately 2 to 6 miles east of the Front Range of Colorado (Figure A-1) on the western margin of the Colorado Piedmont section of the Great Plains Physiographic Province (Spencer, 1961). The geologic history of the Rocky Mountain region of Colorado (which includes the Site area) has been summarized by Haun and Kent (1965). The elevation at the Site is approximately 6,000 feet above mean sea level (msl). The Industrial Area (main facility area) of the Site is located on alluvial-covered pediment. The upper surface of the alluvium slopes easterly one to two degrees. Most of the surrounding area in the Buffer Zone is more prominently dissected with intermittent streams. These small, eastward flowing streams include Rock Creek, Walnut Creek, Woman Creek, and several surface water diversion ditches (see Section 3.1.4 of this report, Figure 3-1).

The following major geologic and hydrologic parameters influence groundwater flow at the Site (EG&G, 1995a):

- Topography controls the surface waters of the upslope drainage basin that, in part, recharges groundwater and the three principal streams draining the Site. The majority of shallow groundwater is intercepted by these drainages.
- The lithology and permeability of the unconsolidated surficial deposits permit meteoric waters to recharge the water table. The water table is contained in alluvium and weathered bedrock.
- Paleotopography of the bedrock pediment, which is less permeable than the overlying unconsolidated surficial deposits, serves to focus groundwater movement along bedrock "lows."
- Paleoweathering of shallow bedrock materials has enhanced the permeability of the upper 10 to 60 feet relative to unweathered bedrock.
- The permeability of bedrock units, composed primarily of claystone with lesser amounts of siltstone and sandstone, is generally several orders of magnitude less than for unconsolidated surficial deposits. The 600+ feet of unweathered bedrock between the shallow groundwater flow system and deep regional Laramie-Fox Hills aquifer provides an effective barrier to vertical groundwater and contaminant movement.

C.1.2 Stratigraphy

The stratigraphic sequence that underlies the Site extends from the crystalline Precambrian gneiss, schist, and granitoids at 3,000 feet below msl to the unconsolidated Quaternary deposits at

surface approximately 6,000 feet above msl. Based upon aerial photographic interpretation, field geologic mapping, coal and aggregate mine development, petroleum exploration in the vicinity, and numerous borehole investigations, a substantial amount of lithologic information has been gained about the Site. The generalized lithologic section in the Rocky Flats area is shown in Figure C-1.

Bedrock formations from the uppermost Cretaceous Pierre, Fox Hills, Laramie, and Arapahoe Formations are present and exposed at the surface and beneath the Site. The Quaternary Rocky Flats Alluvium, and to a limited extent Verdos Alluvium, unconformably overlie the Cretaceous Arapahoe and Laramie Formations in the central portion of the Site. The unconsolidated surficial deposits, combined with the weathered portion of subcropping bedrock formations, form the sequence of rocks which have the greatest importance regarding groundwater flow and contaminant transport at the Site.

C.1.2.1 Pediment-Covering Alluviums

Several Quaternary alluvial formation pediment covers have been identified in the vicinity of the Site by Scott (1975). The Rocky Flats Alluvium is an unconsolidated deposit derived from quartzites and granites of the Coal Creek Canyon provenance west of the Site. The deposit diminishes from west to east with thicknesses ranging from approximately 100 feet to less than 1 foot. In the central portion of the Site, the deposit is approximately 15 to 25 feet thick. The Rocky Flats Alluvium is a heterogeneous deposit dominantly composed of angular to subrounded, poorly-sorted, coarse, bouldery-gravel with a clay and sand matrix. Clay, silt, and sand lenses as well as varying amounts of caliche are also present. Exposures of Rocky Flats Alluvium in the aggregate quarries north and west of the Site exhibit some large scale cross-stratification. Depositional processes include fluvial and debris-flow transport (Shroba, 1994) infilling paleotopographic lows but leaving a widespread surface of erosion with extremely low relief.

C.1.2.2 Other Surficial Deposits

In addition to the pediment-forming alluvial deposits, younger Quaternary units consisting of colluvium, landslide alluvium, and valley fill alluvium mantle the hillslopes and valley bottoms below the pediment surface. Colluvial deposits are derived from Arapahoe and Laramie Formations and older alluvial deposits. This unit consists of sheetwash, soil creep, and landslide materials in a total thickness of 3 to 16 feet (Shroba, 1994). These deposits locally flank the Rocky Flats Alluvium and generally extend to lower parts of the slopes along the principal drainages.

Landslide deposits more commonly flank the Rocky Flats Alluvium. They are often bounded by headwall scarps and lobate toes at the downslope margins. Seeps issuing from the base of the Rocky Flats Alluvium contribute to landslide colluvium generation. The landslide units include earth flows, slumps, and debris flows in a thickness estimated between 10 to 33 feet (Shroba, 1994).

C.1.2.3 Arapahoe Formation

The Arapahoe Formation is composed of claystones and silty claystones with some lenticular sandstones. In the Geologic Characterization Report for the U.S. DOE Rocky Flats Plant (EG&G, 1991), the Arapahoe Formation was interpreted to be 150 feet thick in the central area and to contain five sandstones named Sandstones 1 through 5. The thickest and most widespread, uppermost sandstone was defined as the No. 1 Sandstone which was interpreted to be deposited in a fluvial environment. The more recent Site-wide mapping program (EG&G, 1992) determined that the overall Arapahoe Formation is generally less than 25 feet thick in the Site area. The No. 1 Sandstone (EG&G, 1991) was correlated to the basal Arapahoe Sandstone. Lower bedrock sandstones (i.e., Sandstones 2 through 5) in the 1991 Geologic Characterization Report were redefined as lenticular Laramie sandstones as they are texturally distinct from the No. 1 Sandstone by virtue of their high silt and clay content. These lower sandstones have limited hydrologic significance and are currently identified as part of the upper Laramie Formation.

The No. 1 Sandstone, which is currently defined as the basal Arapahoe Sandstone, is of concern as a potential contamination pathway, especially where it subcrops beneath the alluvial/bedrock unconformity. The other sandstones pose a limited threat as potential contamination pathways since they are lenticular and discontinuous.

C.1.2.4 Laramie and Fox Hills Sandstone Formations

The Laramie Formation is approximately 600 to 800 feet thick and is composed of a lower sandstone/claystone/coal interval and an upper, thicker claystone interval. The permeable lower sandstones and coals of the Laramie, combined with the permeable sandstones of the Fox Hills, constitute a regional aquifer system known as the Laramie-Fox Hills aquifer. This aquifer system is an important water source in the South Platte River Basin (Pearl, 1980), and is the sole water supply for some residents in the Rocky Flats area. The Fox Hills Formation is primarily a fine-grained sandstone with an approximate thickness of between 75 to 125 feet with thin siltstone and claystone interbeds. The Fox Hills Formation outcrops and subcrops along a narrow, north-south trending pattern in the extreme western part of the Site upgradient from known sources of contamination.

C.1.2.5 Pierre Formation

The Pierre Formation is a 7,500-foot thick, dark gray, silty bentonitic shale that acts as a lower confining layer for the Laramie-Fox Hills aquifer in the Denver Basin. This thick marine shale unit subcrops only in the extreme western part of the Site.

C.1.3 Geologic Structure

The Site is located along the western margin of the Denver Basin, an asymmetric basin with a steeply east-dipping western flank and a gentle eastern flank. The interpretation of the subsurface

structure is generalized in the east-west geological cross section of the Site area presented in Figure C-2. A monoclinial fold limb exposed west of the Site is the most significant surficial structural feature in the Site area. Along the west limb of the fold, an angular unconformity exists between the Upper Cretaceous bedrock and the base of the Quaternary Rocky Flats Alluvium.

No active faults have been identified at the Site. Several high angle bedrock faults have been inferred to exist in the Industrial Area of the Site based on various stratigraphic and borehole correlation criteria. These faults appear to have only a limited hydrologic significance with regard to vertical groundwater movement and contaminant transport (DOE, 1996).

C.2 Hydrogeology

C.2.1 Introduction

This section presents the basic concepts about the hydrogeologic conditions at the Site that affect groundwater monitoring and protection. Characterization of the hydrogeologic setting is based on the currently accepted conceptual geologic and hydrogeologic models described in the Sitewide Geoscience Characterization Study (EG&G, 1995b, Shroba, 1994, EG&G, 1995c). These conceptual geologic and hydrogeologic models are used to predict the direction and rate of groundwater flow, identify potential pathways for contaminant migration, and determine the extent of contaminant plumes given varying physical, chemical, and biological factors.

C.2.2 Definition of the Uppermost Aquifer for the Site

The term "aquifer" as defined by Title 40 of the *Code of Federal Regulations* (CFR) Section 260.10 is a "geologic formation, group of formations, or a part of a formation that is capable of yielding a significant amount of water to a well or spring." An "uppermost aquifer" is defined as "the geologic formation nearest the natural ground surface that is an aquifer, as well as lower aquifers that are hydraulically interconnected with this aquifer within the facility's boundary." Geologic materials with similar hydrologic properties comprise a hydrostratigraphic unit (HSU) (Fetter, 1988). For purposes of this report, the uppermost aquifer or upper hydrostratigraphic unit (UHSU) consists of the unconfined saturated zone, in which unconsolidated and consolidated groundwater-bearing strata are in hydraulic communication. The UHSU consists of the following geologic units: Rocky Flats Alluvium, valley-fill alluvium, colluvium, landslide deposits, weathered Arapahoe and Laramie Formation bedrock, and all sandstones within the Arapahoe and upper Laramie Formations in hydraulic communication with the overlying unconsolidated surficial deposits. The UHSU is considered to be equivalent to the uppermost aquifer at the Site.

Beneath the surficial materials and the consolidated sandstones of the UHSU are the geologic units of the lower hydrostratigraphic unit (LHSU). The LHSU consists of the consolidated, unweathered bedrock zone of the Arapahoe and upper Laramie Formations not in hydraulic communication with the overlying UHSU. The Arapahoe and upper Laramie Formations comprising the geologic units of the LHSU consist of lesser amounts of sandstone and greater amounts of adjacent claystones. Because of the low permeability of the claystones, they behave as aquitards restricting hydraulic communication with the UHSU. The lower Laramie and Fox Hills Formations comprise a stratigraphically lower and third hydrostratigraphic unit beneath the Site.

Groundwaters of the three hydrostratigraphic units are hydraulically separated beneath the Industrial Area of the Site. They do converge, however, and are in mutual contact immediately upgradient near the western margin of the Site due to monoclinal folding and erosional proximity. Initially, background geochemical characterization of the UHSU and LHSU revealed the units as having statistically different groundwater chemistry concurring with the delineation of separate hydrostratigraphic units (EG&G, 1993a). This concept is presently being qualified. In addition, possible communication of the hydrostratigraphic units along other geologic structures is currently being assessed. More detailed differentiation of the LHSU will be achieved as new hydrogeologic and geochemical data are generated from Site investigations currently proposed or in progress.

C.2.3 Groundwater Occurrence and Distribution

The Site is located in a regional groundwater recharge area (EG&G, 1991). Groundwater recharge occurs from the infiltration of incident precipitation and as base flow near the upgradient area of the Site drainage basin, which extends west to Coal Creek. Groundwater recharge occurs from the infiltration of precipitation and from stream, ditch, and pond seepage. Much of the groundwater that discharges from the UHSU to streams and seeps evaporates as it is being discharged. Limited investigation of the former Operable Unit (OU) 2 area during the period of July through October 1993 indicated that the precipitation component of recharge was lost to evapotranspiration demands (EG&G, 1993b).

In the western part of the Site, where the thickness of the Rocky Flats Alluvium reaches 100 feet, the depth to the water table is 50 to 70 feet below the surface. The depth to water generally becomes shallower from west to east as the alluvial material thins and the confining claystones approach the ground surface. At the head of stream drainages and valley sides, seeps are common at the base of the Rocky Flats Alluvium where it is in contact with claystones of the Arapahoe/Laramie Formations, and where Arapahoe Formation sandstone crops out. In general, the unconsolidated surficial materials are thicker in the western, higher elevations at the Site. Accordingly, the saturated thickness of these materials also thins eastward. The potentiometric surface of groundwater in unconsolidated surficial deposits has been mapped and is shown on Plate 2. The period illustrated represents the time of year when static water levels are highest. Extensive areas of unsaturated and seasonally unsaturated alluvium and colluvium are indicated east and northeast of the Industrial Area.

Groundwater in the Arapahoe Formation sandstone units, which subcrop beneath the alluvial material, is not confined when in contact with the surficial materials. In this setting, a hydraulic connection exists between the bedrock sandstone and the alluvial material allowing the bedrock groundwater to exist under unconfined conditions as part of the UHSU. The subcropping Arapahoe Formation No. 1 Sandstone located in the eastern portion of the Industrial Area and in the area between South Walnut Creek and Woman Creek is part of the UHSU (EG&G, 1991). The upper discontinuous sandstones of the Laramie Formation also subcrop beneath alluvium and colluvium, but in limited areas in the valleys and along valley slopes. Groundwater in the lenticular sandstone units of the Laramie Formation occurs under confined conditions over scattered areas of the Site.

Groundwater levels in UHSU wells fluctuate in response to seasonal recharge events. Approximately 15% of the groundwater monitoring wells commonly are dry during at least one of the quarterly sampling events. Of the remaining wells, approximately half cannot yield sufficient water volume (4.5 gallons) specified for laboratory samples. Sampling crews must return later after wells have recovered and obtain additional sample volumes.

C.2.4 Groundwater Flow

The shallow groundwater flow regime at the Site is illustrated by the configuration of potentiometric contours in Plate 2. This map indicates that groundwater flow is largely controlled by the topography of the bedrock surface. Groundwater in the ridge tops generally flows toward the east-northeast. In areas where the ridge tops are dissected by east-northeast trending stream drainages, groundwater flows to the north or south toward the bottom of the valleys. In the valley bottoms, groundwater flows to the east, generally following the course of the stream. Shallow groundwater flow is primarily lateral due to the low permeability of the underlying claystone bedrock.

A potential for vertical groundwater flow, although limited by the low permeability of bedrock claystones, is indicated by the presence of strong downward vertical hydraulic gradients between the UHSU and underlying bedrock units. This situation implies a condition of poor hydraulic communication. For example, vertical gradients on the order of 0.79 to 1.05 feet per foot (ft/ft) have been calculated between colluvial and bedrock sandstones at OU1. The vertical groundwater flux through claystones is assumed to be small, on the order of 10^{-10} to 10^{-7} centimeters per second (cm/sec), based on calculations provided (DOE, 1996). Fracturing, where evident, is most abundant in the weathered bedrock zone, but is observed to decrease with depth in unweathered bedrock. Preferential vertical groundwater flow and contaminant transport along fractures or fault zones do not appear to represent a viable pathway for contaminant migration based on an assessment of available data (DOE, 1996).

C.2.5 Hydraulic Conductivity

The UHSU at the Site has a relatively low to moderate hydraulic conductivity that typically yields small amounts of water to groundwater monitoring wells. The UHSU exhibits a wide range of

hydraulic conductivities because of the diverse nature of the individual geologic units that comprise this unit. Summary statistics for UHSU hydraulic conductivities [(EG&G, 1995c) Table G-2] indicate a range of 5.0×10^{-2} cm/sec [3.0×10^4 feet per year (ft/yr)] to 3×10^{-8} cm/sec (9.3×10^{-1} ft/yr). Listed in order of decreasing geometric mean hydraulic conductivity, the relative ranking of individual units of the UHSU is presented as follows: valley-fill alluvium (2.5×10^3 cm/sec), Arapahoe No. 1 sandstone (7.9×10^{-4} cm/sec), Rocky Flats Alluvium (2.1×10^{-4} cm/sec), colluvium (9.3×10^{-5} cm/sec), weathered Laramie Formation sandstones (3.9×10^{-5} cm/sec), and weathered Laramie Formation claystones (8.8×10^{-7} cm/sec). Hydraulic conductivities for LHSU materials are generally the lowest measured at the Site with geometric mean values for individual lithologic groups ranging from 1.6×10^{-7} to 5.8×10^{-7} cm/sec [(11), Table G-2]. The low permeability and 600+ foot thickness of the upper Laramie Formation claystones act as an effective aquitard that restricts downward vertical groundwater flow and contaminant transport to the Laramie-Fox Hills aquifer (DOE, 1996).

D.1 Impact of Individual Hazardous Substance Sites on the Quality of Groundwater

The characterization and assessment of Individual Hazardous Substance Sites (IHSSs) and their potential to impact groundwater and surface water has historically been conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) remedial investigation/feasibility study (RI/FS) programs for individual Operable Units (OUs). In 1995, the decision was made to take a Site-wide approach to the evaluation and remediation of the Rocky Flats Environmental Technology Site (RFETS or the Site). Of the original 16 OUs, there are only 7 OUs remaining: the Buffer Zone OU, the Industrial Area OU, and OUs 1, 3, 5, 6, and 7. However, groundwater issues will be investigated on a Site-wide basis.

The general conclusions reached with respect to groundwater contamination are that the hydrogeologic setting of a specific area directly affects the movement and quality of groundwater. Chemicals at some of the Site IHSSs have impacted groundwater quality. To characterize this impact, groundwater quality data have been compiled to identify hazardous constituents, determine their concentrations and rate of migration, and delineate the horizontal and vertical extent of potential contaminant plumes. The migration of contaminants can be highly influenced by engineered structures such as buildings, dams, slurry walls, diversion drains, pipelines, and diversion flumes that affect natural, near-surface water movement at the Site.

Because so much of the information dealing with individual IHSSs and contaminant sources is referenced in documents pertaining to the OUs, a short description and references pertinent to the OU where plumes exist is provided in this section. Summaries of groundwater analytical data for determination of historic chemicals of concern is presented in Table D-1.

D.2 Groundwater Contaminant Plumes

Evaluation of geochemical data from groundwater wells sampled as part of the Site-wide monitoring program has delineated a number of areas of groundwater contamination. The most widespread contamination is that of volatile organic compounds (VOCs). Plate 3 shows the distribution of VOC contamination in the upper hydrostratigraphic unit (UHSU). Plume definition is inexact, however, because of limitations in well coverage, variability of hydrostratigraphic conditions, and local variations in groundwater transport velocity. Published plume maps for individual constituents can be found in the 1993 *Well Evaluation Report* (EG&G, 1994a), the annual RCRA groundwater reports [EG&G, 1992, 1993, 1995, Rocky Mountain Remediation Services (RMRS), 1996a], and in individual OU RI/Resource Conservation and Recovery Act (RCRA) feasibility investigation (RFI) reports.

The VOC contaminant plumes in groundwater at the Site have the most potential to impact surface water or to migrate off Site. These plumes have been defined on the basis of exceedances above the maximum contaminant levels (MCL) for individual constituents. To delineate areas of highly contaminated groundwater, the groundwater action levels of 100 times the MCLs were compared against all groundwater data for the most common VOCs in groundwater. The

RFETS Integrated Monitoring Plan

exceedances were plotted and are shown on Plate 3. The most probable sources were identified using the results of recent field sampling programs and process knowledge (RMRS, 1996b). A flow diagram (RMRS, 1996b) describes the method used to locate the contaminant plumes and corresponding sources, and to determine which areas should be targeted for remedial action. Other contaminants also will be addressed where there is an impact to surface water exceeding action levels.

There are six groundwater contaminant plumes identified where contaminant concentrations exceed 100 times the MCLs. These groundwater contaminant plumes include 1) IHSS 119.1 Plume, 2) Mound Plume, 3) 903 Pad and Ryan's Pit Plume, 4) Carbon Tetrachloride Plume, 5) East Trenches Plume, and 6) Industrial Area Plume. In addition, there are three plumes with contaminant concentrations that do not exceed 100 times the MCLs, but that have the potential to impact surface water. These plumes are the Existing (Present) Landfill, Solar Ponds, and the Property Utilization and Disposal (PU&D) Yard Plumes (RMRS, 1996b).

D.2.1 Groundwater Contamination at 881 Hillside (OU1)

The 881 Hillside is located in the south-central portion of the Site on the north slope of Woman Creek as shown on Figure A-3. Figure D-1 presents detail of the IHSSs for OU1. The area was selected as a high priority site because of the elevated concentrations of VOCs detected in the alluvial groundwater, the relatively permeable soils, and the proximity to Woman Creek. The *Final Phase III RFI/RI Work Plan Revision 1, Rocky Flats Plant 881 Hillside Area OU1* (EG&G, 1991), outlines the activities that were required to identify the extent of contamination.

D.2.1.1 Individual Hazardous Substance Site 119.1 Plume

The drum storage area (IHSS 119.1) within OU1 is the site of historic releases of chlorinated VOCs to the environment. These releases have resulted in the contamination of shallow alluvial groundwater (i.e., the UHSU) and have formed a small, relatively stable contaminant plume extending down the 881 Hillside. Trichloroethylene (TCE), perchloroethylene (PCE), and 1,1,1 trichloroethane (TCA) are the most common organic contaminants at 881 Hillside.

In 1992, a French drain was installed to intercept contaminated groundwater perceived to be flowing down the 881 Hillside. The French drain is excavated as deep as 28 feet into bedrock and intercepts UHSU groundwater flowing in paleotopographic depressions. A three-foot diameter recovery well located within the source area also was installed to recover water containing high levels of dissolved VOCs.

The French drain is still in operation and is collecting relatively uncontaminated groundwater for treatment at the Building 891 Treatment Plant. The plume is upgradient of the French drain and does not appear to be migrating. The area immediately downgradient of the French drain is unsaturated, indicating that the French drain has dewatered much of the area. A small seep

Figure D-1
Individual Hazardous Substance Sites of OU1

located south of IHSS 119 1 and downgradient of the French drain along Woman Creek was sampled once. This sample contained a trace amount of VOCs. However, it is not clear if the VOC concentrations in the seep water are related to the contaminant plume.

Groundwater in the unweathered bedrock at 881 Hillside did not appear to be impacted by contaminants transported by the alluvial groundwater system.

Information on groundwater quality for the French drain is documented in quarterly reports that have been produced as required in the French drain interim measures/interim remediation action (IM/IRA) (DOE, 1992a). Additional information on 881 Hillside is reported in the *OUI Phase III RFI/RI Work Plan Revision 1* (EG&G, 1991) and in the *OUI Final Phase III RFI/RI* (DOE, 1994a).

D.2.2 Groundwater Contamination Associated with the Former OU2

IHSSs grouped within the former OU2 are shown in Figure A-3. Figure D-2 presents details of the IHSSs for OU2. The 903 Pad is located in the southeast corner of the Site south of the inner east gate. The Mound is located north of Central Avenue at the southeast corner of the Protected Area. The East Trenches straddle the East Access Road, east of the inner east gate.

The 903 Pad and the Mound were historically used for the storage and burial, respectively, of radioactively contaminated wastes. Radioactively contaminated sludge and other materials were buried in the trenches (DOE, 1992b). The 903 Pad and Ryan's Pit Plume, Mound Plume, and East Trenches Plume are part of a large composite plume on the east side of the Site. Even though these contaminant plumes overlap, differing sources and flow paths make it effective to treat these parts of the large plume individually.

D.2.2.1 Mound Plume

The Mound site groundwater contaminant plume is poorly defined, but it is suspected to extend northward from the former location of the Mound where drums were buried to a point of discharge along South Walnut Creek, upstream of the Site Sewage Treatment Plant. Depending on the season, there may be many unsaturated areas within the plume. Dense nonaqueous phase liquids (DNAPLs) in the Mound area are suspected to be the source of the groundwater contamination and the potential exists for contaminant concentrations to increase over time. There is a possibility that Trench 1 could contribute to this plume, however, evidence indicates that the Mound site is the primary source.

Contaminated groundwater from the plume contains vinyl chloride, tetrachloroethene, and trichloroethene. The contaminant plume is discharging through surface and subsurface seepage into South Walnut Creek. The contaminated groundwater discharges at a rate of 0.5 gallons per minute (gal/min) or less at seep SW059, where it is collected and stored, then later treated at the Building 891 Treatment Plant.

Figure D-2
Individual Hazardous Substance Sites of OU2, 903 Pad, Mound, and East Trenches

D 2 2 2 903 Pad and Ryan's Pit Plume

This contaminant plume has two, closely spaced sources 1) VOCs associated with drums formerly stored at the 903 Storage Area, where the contents of the drums leaked into the subsurface and groundwater, and 2) Ryan's Pit where VOCs were disposed of in a trench The contaminated groundwater flows southward from these two source areas, toward the South Interceptor Ditch and Woman Creek The groundwater is contaminated with carbon tetrachloride, tetrachloroethene, trichloroethene, and other VOCs The highest concentrations of VOCs in groundwater are near the 903 Pad and Ryan's Pit sources, although isolated areas of high concentration have been observed within the plume away from these sources Pure-phase tetrachloroethene and motor fuel constituents were found during the excavation of Ryan's Pit Pure-phase DNAPLs are also suspected to exist underneath the 903 Pad

Groundwater flow paths in alluvial materials in the 903 Pad and Ryan's Pit area are relatively well defined by contact seeps with the underlying bedrock materials and by numerous wells However, groundwater flow through the hillside colluvium and bedrock is poorly understood Areas of unsaturated colluvium are fairly common and prediction of local flow paths is difficult Depending on the season, there may be many unsaturated areas within the plume Discharge of contaminated groundwater has not been observed from the colluvium or weathered bedrock portion of this plume

Contaminated groundwater containing tetrachloroethene and trichloroethene may eventually enter the South Interceptor Ditch and Woman Creek surface water pathways if no actions are taken to manage this plume Discharge of contaminated groundwater into Woman Creek would pose a potential risk to the environment Collection and treatment of contaminated groundwater from the 903 Pad and Ryan's Pit Plume will reduce the risk to the environment posed by uncontrolled releases to surface water

D 2.2 3 East Trenches Plume

A large plume of contaminated groundwater is located in the East Trenches area The principal sources are IHSS 110 (Trench 3) and 111 1 (Trench 4), with a minor contribution from the VOCs in the 903 Pad area The trenches were used to bury sewage sludge from the Sewage Treatment Plant, but also contain DNAPLs, crushed drums, and other miscellaneous waste Contaminated groundwater occurs within the UHSU, in the alluvium, and in the bedrock sandstone that is in hydraulic connection with the alluvium The major contaminants are carbon tetrachloride, tetrachloroethene, and trichloroethene, as well as other VOCs

The downgradient boundary of the contaminant plume is located at a spring-and-seep complex on the south bank of South Walnut Creek above Ponds B1 and B2 where the bedrock sandstone subcrops Concentrations of VOCs above 100 times the MCLs have been detected by a recent sampling program conducted at the seep complex There are potential ecological impacts because water from the contaminant plume containing tetrachloroethene and trichloroethene has reached

South Walnut Creek If concentrations in the seep complex increase over time, a greater contaminant mass may reach surface water

A lobe of this contaminant plume also extends to the east of the East Trenches area in the alluvium, but has not reached surface water Uncontaminated alluvial groundwater discharges downgradient of this lobe as seeps in an unnamed tributary drainage to South Walnut Creek This groundwater will continue to be monitored

Additional background information on groundwater quality for OU2 is reported in the *Phase II RI/FS Work Plan, Rocky Flats Plant, 903 Pad, Mound, East Trenches Areas OU2* (Rockwell, 1989) and in the *Final Phase II RFI/RI OU2 Report* (DOE, 1995)

D.2.3 Solar Evaporation Ponds Groundwater Contamination (OU4)

The Solar Evaporation Ponds (SEPs)(IHSS 101) are located in the northeast section of the Protected Area as shown in Figure A-3 Figure D-3 presents details of the IHSS for OU4 The groundwater flow beneath the SEPs originates southwest of the Industrial Area and diverges flowing toward unsaturated areas above Walnut Creek and South Walnut Creek as shown on Plate 2

The five ponds at IHSS 101 were used to temporarily store and treat various process aqueous wastes by evaporation This included waste streams with low-level radioactivity, nitrates, acids, and sewage effluent The configuration of these ponds has changed several times since they were initially installed in 1953 Previous hydrologic investigations of the SEP area indicated that the groundwater had been impacted by leakage from the ponds

D 2.3.1 Solar Ponds Plume

Because contaminants were detected downgradient of the SEPs, a RCRA Assessment Groundwater Monitoring Program was instituted Table D-1 lists contaminants detected in downgradient wells as reported in the annual RCRA groundwater monitoring reports (EG&G, 1992, 1993, 1994b, 1995, RMRS, 1996a) Groundwater monitoring data from UHSU wells indicate that nitrate contamination from the SEPs has migrated downgradient of the ITS in unconsolidated surficial deposits and weathered bedrock

The released nitrates have contaminated UHSU groundwater and have formed a plume that extends northward from the SEPs to the North Walnut Creek drainage above Pond A1 (see Plate 3) A small lobe of this nitrate plume extends to the southwest for a short distance This contaminant plume contains nitrates at concentrations above 100 times the MCLs Nitrate concentrations within the plume are decreasing with time but still exist at high levels The analytical data indicate that the maximum concentrations of all the contaminants occurred in the immediate area of the SEPs with concentrations declining rapidly downgradient

Figure D-3
Individual Hazardous Substance Sites OU4

In response to nitrate/nitrite contamination detected in Walnut Creek, a series of trenches and sumps were installed north of the SEPs from 1971 to 1974. The trenches and sumps were replaced by a more extensive interceptor trench system (ITS) in the early 1980s. The purpose of this ITS was to collect surface water and shallow groundwater immediately downgradient of the SEP area. Water collected by the ITS was originally transferred back to one of the SEPs (Advanced Sciences, 1991), but now the ITS water is pumped to the Building 374 treatment system. The ITS was replumbed in 1993 to increase its effectiveness. The ITS captures approximately 2.7 million gal of water per year but is not entirely effective in preventing nitrate contamination from impacting the North Walnut Creek drainage (DOE, 1994b).

Drainage of liquids and removal of sludge were completed at SEPs 207-A, 207-B North, 207-B Central, and 207-B South in 1994. The remaining pond, 207-C, has been drained and sludge has been removed to on-Site storage tanks.

The *Annual RCRA Groundwater Monitoring Reports for Regulated Units at the Site* contain available analytical data for the SEPs (EG&G, 1992, 1993, 1994a, 1995). Data are available for the second quarter 1988 through 1995. Additional information can be found in the *Draft IM/IRA Decision Document for OU4 Solar Evaporation Ponds* (EPA, 1994b) and the *OU4 Solar Evaporation Ponds Phase II Groundwater Investigation Final Field Program Report* (DOE, 1996a).

D.2.4 Industrial Area Groundwater Contamination

The Industrial Area has not received the same level of characterization as other portions of the Site. This is because the OUs associated with the Industrial Area had not completed RFI/RI investigations before the decision was made to integrate all remedial activities at the Site. Prior to the elimination of the OU-based investigations, OUs 8, 9, 10, 12, 13, and 14 were combined for purposes of remedial investigation. Preliminary surface soil investigations had been completed prior to cessation of activities on the Industrial Area OUs but no groundwater investigation had been started. However, two groundwater plumes have been generally defined, the Carbon Tetrachloride Plume and the Industrial Area Plume.

D.2.4.1 Carbon Tetrachloride Plume

Preliminary borehole drilling around tanks T9 and T10 in the former OU8 uncovered carbon tetrachloride free product that is associated with the Carbon Tetrachloride Plume. The carbon tetrachloride spill (IHSS 118.1) is located due north of Building 776 and east of Building 730. There are several documented past releases of carbon tetrachloride at this site. This area also overlaps other IHSSs [1 e, 121-T9, 121-T10, 131, and 144(N)]. Different spills are associated with these IHSSs.

IHSS 118 1 is the site where a 5,000-gal, underground steel storage tank for carbon tetrachloride and associated piping were formerly located. Numerous reported spills have occurred before 1970, some between 100 to 200 gal, as documented in the Historical Release Report (DOE, 1992b). The tank ultimately failed in June 1981 and subsequently was removed along with a limited amount of soil surrounding the tank. The numerous releases of carbon tetrachloride from IHSS 118 1 have contaminated surrounding soils and formed a contaminant plume in UHSU groundwater which extends from the vicinity of the former tank location eastward to the SEPs. The plume may eventually reach the Walnut Creek drainage.

D.2.4.2 Industrial Area Plume

The IM/IRA for the Industrial Area (DOE, 1994c) compiled groundwater and surface water data for use in designing a monitoring program for decontamination and decommissioning (D&D) activities. From these data, a groundwater plume composed of VOCs was discovered in groundwater in the Buildings 300 and 400 areas that later was defined as the Industrial Area Plume (see Plate 3). The Industrial Area Plume is suspected to be a coalesced plume of contaminated groundwater containing trichloroethene thought to emanate from IHSSs 117 1, 117 2, 157 1, 158, 171 and 182, tetrachloroethene thought to emanate from IHSSs 117 1, 117 2, 158, 157 1, 160, and 171, and carbon tetrachloride thought to emanate from IHSSs 117 1, 117 2, and 158.

Currently, the Industrial Area Plume does not appear to be migrating rapidly downgradient, and there are no known surface water impacts. However, groundwater pathways exist to both Woman Creek and to Walnut Creek. Groundwater recharge in the Industrial Area caused by water losses from sewers and water-supply pipelines may be substantial. Reduction of recharge from these sources could significantly reduce the potential for contaminant migration in the subsurface.

Treatment of contaminated groundwater within the Industrial Area does not appear to be necessary to protect surface water because the plume appears to have limited potential for migration. However, ongoing monitoring and evaluation of the groundwater through the monitoring program will continue and will detect any possible movement or expansion of the plume. Groundwater remedial actions may become necessary if the contaminant plumes expand and migrate significantly, thereby becoming a threat to surface water.

Further investigation of the plume or plumes in the Industrial Area has been suspended until D&D activities have been completed on buildings in the Industrial Area. Wells in the Industrial Area will be monitored for the known contaminants detected in the Industrial Area Plume.

D.2.5 Groundwater Contamination at the Existing Landfill (OU7)

The Existing (Present) Landfill began operation in 1968 with the closure of the Original Landfill (now IHSS 115). The Existing Landfill is located in the Buffer Zone north of the Protected Area as shown on Figure A-3. Figure D-4 presents detail of the IHSSs included in OU7. The local recharging groundwater flow direction is from the west-southwest toward the Existing Landfill, then is focused toward the Landfill Pond and the portion of the Walnut Creek drainage designated as "No Name Gulch" as shown on Plate 2.

In addition to typical sanitary landfill wastes, limited quantities of hazardous wastes were disposed of in the landfill, particularly in the early years of operation between 1968 and 1970. In September 1973, tritium was detected in leachate draining from the landfill. In response, a sampling program was initiated to determine the location of the tritium source and interim response measures were also undertaken to control the generation and migration of landfill leachate. Interim response measures included the construction of two ponds, of which the East Landfill Pond remains, and a subsurface leachate collection system and a subsurface intercept/slurry wall system for diverting upgradient groundwater.

Evaluation of groundwater quality data (EG&G, 1994) specifically within the Existing Landfill revealed elevated radionuclide activities and high concentrations of VOCs, metals, and inorganic constituents. The Existing Landfill has been under a RCRA Alternate Groundwater Monitoring Program. Table D-1 lists the chemicals detected in the Existing Landfill based on data generated from the groundwater monitoring program. Aluminum, manganese, zinc, 2-methylnaphthalene, naphthalene, benzene, and possibly methylene chloride are present in leachate below the current landfill, with average values exceeding action levels. Organic contaminant plumes exist in groundwater south and west of the current landfill pond, including a portion of OU7. Groundwater in downgradient wells below the landfill pond show elevated concentrations of nitrate, sulfate, chloride, lithium, barium, strontium, magnesium, and uranium with respect to upgradient wells (RMRS, 1996a).

D.2.5.1 PU&D Yard Plume

In 1993, newly installed upgradient wells at the Process Simulation Laboratory (PSL) detected significant concentrations of VOCs in the alluvial groundwater. These data and data from wells on the south side of the PSL suggest that a VOC plume exists upgradient of the PSL and has migrated eastward (see Plate 3). The suspected source of the contamination is the PU&D yard located west of the landfill. Activities are being planned to evaluate the source of this plume.

Additional information on water quality at the PSL can be found in the *Annual RCRA Groundwater Monitoring Reports For Regulated Units* (EG&G, 1992, 1993, 1994a, 1995, RMRS, 1996a), *Technical Memorandum - Final Work Plan for OU7* (DOE, 1994d) and *Draft IMIRA Decision Document for OU7 Present Landfill* (DOE, 1996b).

Figure D-4
Individual Hazardous Substance Sites Near OU7

D.2.6 Old Landfill (OU5)

The Old Landfill (OLF) is geographically located along the north side of Woman Creek and is designated as IHSS 115. The OLF was investigated as part of the OU5 RFI/RI project (DOE, 1996c). Figure A-3 shows the IHSSs covered in OU5.

Elevated concentrations of a few metals, water quality parameters, radionuclides and VOCs were encountered in wells monitoring the OLF (see Table D-1). TCE and TCA were the only volatile organics encountered. Though contamination from the OLF is at low levels, and a downgradient contaminant plume has not been defined, the proximity of the IHSS to Woman Creek has made it a priority for monitoring.

4.0 AIR MONITORING

4.1 Introduction

Regulatory activities encompassed by federal and state regulations established pursuant to the Clean Air Act (CAA) and its amendments are managed and directed at the Rocky Flats Environmental Technology Site (RFETS or Site) by the Air Quality Management (AQM) group within Kaiser-Hill Company's (Kaiser-Hill) Environmental Compliance and Operations (ECO) organization. AQM is responsible for developing compliance, reporting, and recordkeeping strategies that organizations on Site use to maintain compliance with applicable air quality regulations and Department of Energy (DOE) Orders. Within that framework, AQM operates effluent, ambient, and meteorological monitoring programs that support both compliance demonstration and emergency response needs at the Site. Additional air monitoring is performed by the Colorado Department of Public Health and Environment (CDPHE) or coordinated by DOE.

The goal of the Site air quality program is to provide a means to assess the impact of Site operations on the air quality, on and around the Site, and thereby protect the public and the environment. These monitoring programs contribute to the Site-wide environmental protection program by providing data that can be used to quantify and/or characterize the air pathway impact on public receptors.

4.1.1 Air Monitoring Objectives and Regulatory Drivers

Air monitoring programs, on and around the Site, fulfill multiple objectives. In many cases, those objectives are mandated by CAA regulations or by DOE Orders. Regulatory drivers pertinent to air monitoring programs include:

- Effluent Monitoring
 - Title 40 of the *Code of Federal Regulations (CFR)*, Part 61, Subpart A "General Provisions," Subpart H "National Emission Standards for the Emissions of Radionuclides Other Than Radon From DOE Facilities" [Rad NESHAPs]), and Appendix B,
 - Colorado Air Quality Control Commission (CAQCC) Regulation No. 8, Part A, Subpart A, "General Provisions," Subpart C, "National Emission Standard for Beryllium," and Subpart H, "National Emission Standards for Emissions of Radionuclides Other Than Radon From Department of Energy Facilities," and
 - DOE Order 5400.1, *General Environmental Protection Program*, U.S. Department of Energy

- Ambient Monitoring
 - DOE Order 5400 5, *Radiation Protection of the Public and the Environment*, U S Department of Energy (Ch 1 10), and
 - 40 CFR 61, Subpart H and CAQCC Regulation No 8, Part A, Subpart H (ambient monitoring proposed as alternative compliance demonstration method)
- Meteorological Monitoring
 - 40 CFR 61, Subpart H and CAQCC Regulation No 8, Part A, Subpart H (meteorological parameters used as input to compliance dispersion modeling),
 - DOE Order 5400 1-IV, 2 4, *General Environmental Protection Program*, U S Department of Energy, and
 - DOE Order 5500 3A, *Emergency Planning and Preparedness for Operational Emergencies*, U S Department of Energy

Air monitoring is performed to comply with regulatory requirements and to support the assessment of Site operations, either directly, as is the case with the effluent monitoring program, or indirectly, as with ambient and meteorological monitoring. For example, while monitoring of radioactive emissions from building process vents fulfills monitoring and reporting requirements of both DOE Orders and Rad NESHAP regulations, the effluent data collected also supports Nuclear Safety evaluations of the building safety envelope.

Effluent monitoring also supports as low as reasonably achievable (ALARA) principals. These DOE principals provide a conceptual radiation exposure guideline intended to encourage radiation protection practices that exceed those of any prescribed standard. The basis for this concept is the acknowledgment that low exposure dose-effect relationships may exist that cannot be measured or demonstrated scientifically. Effluent monitoring is used to verify the efficacy of radiation control mechanisms that are used in the areas containing and handling significant quantities of radionuclide materials. Levels of emissions that cause no concern from an environmental regulatory perspective are sufficient to trigger a proactive investigative response under the ALARA concept.

Ambient monitoring of radionuclides on the Site and at the perimeter is performed by AQM and by CDPHE. Ambient monitoring in the communities immediately adjacent to the Site is coordinated by DOE, as explained below.

Ambient monitoring satisfies DOE Order requirements and, in the future, will be used to satisfy Rad NESHAP reporting requirements. Ambient data can be used in human health risk assessment evaluations of Operable Unit closure. Data from ambient monitoring are also used to validate

projections made by dispersion modeling. In addition, ambient data from the Site's Radioactive Ambient Air Monitoring Program (RAAMP) are used to confirm that controls are operating within Nuclear Safety's ALARA limits, under the DOE directive that strives to keep dose to all receptors as low as reasonably possible by maintaining administrative and mechanical controls on all potential sources of radiological exposure.

On-Site meteorological monitoring supports both the Rad NESHAP reporting requirements and emergency response requirements under the DOE Orders. Meteorological data are currently used for air quality monitoring support, atmospheric dispersion modeling, hydrological studies, construction management, and safety investigations. Emergency response operations and their associated modeling efforts make major use of the on-Site meteorological data.

In cooperation with the surrounding communities, DOE has implemented a five-station Community Radiation (ComRad) Monitoring Program. Independently operated monitoring stations were installed in 1992 in the communities of Arvada, Westminster, Broomfield, and Northglenn. Ambient concentrations of plutonium (Pu), meteorological data, and gamma radiation data are collected continuously using monitoring protocols comparable to those at the Site. Sample analysis is performed by U.S. Environmental Protection Agency (EPA) Region VII laboratories in Las Vegas. Although not a compliance-driven monitoring program, DOE supports this independent evaluation of its potential emissions as a gesture of public assurance of the Site's safe operation.

4.1.2 Site Air Monitoring Scope

The AQM organization provides programmatic support to Site operations to assure compliance with all state and federal laws and regulations originating from the CAA and its amendments, and DOE Orders related to the air impacts of Site operations. The scope of this support includes the characterization of both airborne materials and the meteorology responsible for their transport and dispersion, with monitoring activities playing a major role in this characterization. Criteria for success include completeness of permitting and surveillance activities, no violations of air quality regulations, adequate quality assurance/quality control (QA/QC) of the measurement activities, well-characterized data sets, and full reporting of required information to state and federal regulatory authorities. AQM's air quality monitoring programs do not include sampling conducted to support industrial hygiene or radiation worker safety programs.

4.1.2.1 Effluent Monitoring

At routine (weekly or monthly) intervals, particulate samples from a continuous effluent sampling system are removed from each building exhaust system identified as having a potential to emit radioisotopes to the environment. Each of these 47-millimeter (mm) filters is radiometrically analyzed for long-lived alpha emitters. The concentration of long-lived alpha emitters is indicative of effluent quality and overall performance of the high-efficiency particulate air (HEPA) filtration.

system. If the total long-lived alpha concentration for an effluent sample exceeds the Site action level of 0.02 picocuries per cubic meter (pCi/m³), a follow-up investigation is conducted to determine the cause and to evaluate the need for corrective action.

Historically, at the end of each month, individual samples from each exhaust system were composited into larger samples by location. Beginning in fiscal year 1996 (FY96), samples from minor (insignificant) emission locations have been collected monthly and composited on an annual basis. Filters from significant sources [having the potential to contribute more than 0.1 millirem (mrem) per year (yr) effective dose equivalent (EDE), uncontrolled, to any member of the public] are analyzed on a monthly basis.

Radionuclides are extracted from these filter composites and subjected to radiochemical separation and alpha spectral analysis, which quantifies specific alpha-emitting radionuclides. Analyses are performed for specific isotopes of Pu, uranium (U), and americium (Am). In addition, tritium (H-3) samples are collected three times weekly at five locations. Detection limits are established to ensure that these radionuclides are detected in concentrations under 10% of the regulatory standard, using Appendix E guidelines from 40 CFR 61.

4.1.2.2 Ambient Monitoring

The RAAMP monitors airborne dispersion of radioactive materials from the Site into the surrounding environment. Thirty-five samplers comprise the RAAMP network. Twelve of these existing samplers have been included in a proposal to satisfy regulatory compliance demonstration requirements under the CAA using environmental measurements, the others are used for backup should there be accidental releases from the Site or for determining local impacts from remediation projects. Samplers operate continuously at a volumetric flow rate of approximately 40 cubic feet per minute (ft³/min), collecting airborne particulates on two collection surfaces. Coarse and fine particulates (above and below 10 micrometers diameter) are collected on separate substrates and can be analyzed independently. Selected samples are routinely analyzed for selected isotopes of Pu, U, and Am.

4.1.2.3 Meteorological Monitoring

Meteorological monitoring is conducted on Site by use of a 61-meter (m) tower instrumented at four levels (ground level and 10, 25, and 60 m). It is designed to provide support for routine monitoring and assessments, and emergency response. A redundant, instrumented, 10-m tower is located near the primary tower to provide backup data support.

4.2 Rad NESHAP Compliance Monitoring

The Site must demonstrate compliance with the Rad NESHAP air emission monitoring requirements and dose standards. To demonstrate compliance, the following critical inputs must be evaluated:

Inputs

- Monitored concentrations of Pu-239/240, Am-241, U-233/234, U-238, and H-3 from applicable emission sources,
- Site-specific meteorology for the year that the monitored data are reported,
- Resuspension coefficient for soils,
- Documentation of emissions potential from all unmonitored Site activities having potential to emit radionuclides,
- Verification of low emissions for sources not subject to continuous monitoring requirements, and
- Quality assurance of all monitored data

Boundaries

<i>Spatial</i>	<p>All areas hosting activities on the Site that could impact off-Site populations</p> <p>Current effluent sampling (stack sampling) is occurring at 52 locations within buildings located throughout the Industrial Area</p> <p>RAAMP samplers sited with a density that would typically capture a plume that has a duration of two hours or more (35 locations)</p>
<i>Temporal</i>	<p>Annual dose estimates</p> <p>Quarterly estimates of emissions reported to public</p> <p>Monthly data from significant emission points to generate 12-month rolling average</p> <p>Weekly or monthly alpha-activity screening analyses from effluent sources</p>

Decision Statement

IF The estimated radiological dose to any member of the public is greater than 10 mrem/yr due to Site operations—

THEN The Site is out of compliance

Point sources (significant sources) that have an estimated uncontrolled (without HEPA filtration) potential to result in an EDE to any member of the public greater than 0.1 mrem/yr require continuous effluent monitoring for radionuclides. Current data from this monitoring yield estimated doses that are three orders of magnitude below the regulatory standard at the Site boundary.

IF The Site cannot use standard prescribed monitoring methods to characterize the emissions from a regulated emission source—

THEN The Site must obtain approval for an alternative methodology from the regulatory agency having primacy

The use of ambient monitoring has been proposed as a plausible alternative sampling method to document dose to potential public receptors and demonstrate compliance.

Monitoring Requirements

A continuous effluent monitoring system must be installed and/or activated for analytes identified in above inputs. For point sources (significant sources) that have an estimated uncontrolled potential to result in a dose to any member of the public greater than 0.1 mrem/yr (significant sources), the continuous monitoring system samples are analyzed monthly. Other ducts or vents yielding potential doses that are less than 0.1 mrem/yr (insignificant sources) are at present continuously sampled; these sample filters are collected monthly and analyzed as an annual composite sample from each location.

Detection limit may be defined as "The smallest amount of sample activity using a given measurement process that will yield a net count for which there is confidence at a pre-determined level that activity is present." Table 4-1 shows the minimum detectable activity (MDA) or detection limits for various effluent analyses which are required of the off-Site laboratories that perform the analyses (on a per sample basis). MDA values calculated for individual analyses may vary depending on actual sample volume, chemical recovery, and analytical blank variability.

With approval from EPA Region VIII and CDPHE, ambient monitoring will also satisfy the regulatory requirements to demonstrate compliance with the 10-mrem/yr dose.

standard

Table 4-1
Detection Limits (MDA) for Effluent Air Samples

Parameter	Required Minimum Detectable Activity (per sample) (pCi)	Approximate Sample Volume (m ³)	MDA (pCi/m ³)
Pu-239/240	0.14	7,340	1.91×10^{-5}
U-234	0.59	7,340	8.04×10^{-5}
U-238	0.59	7,340	8.04×10^{-5}
Am-241	0.18	7,340	2.45×10^{-5}
Tritium (H-3)	4.0	190	0.02

Notes

pCi = Picocuries
 Am = Americium
 Pu = Plutonium
 m³ = Cubic meters

MDA = Minimum Detectable Activity
 U = Uranium

Samples from selected ambient sites that can be demonstrated by dispersion modeling to have a reasonable probability of capturing the highest potential ambient concentrations due to source emissions will be collected and analyzed on a monthly basis. Analytes will include Pu-239/240, U-234, U-238, and Am-241. Table 4-2 gives the required analytical detection limits (MDA) for the ambient sampling network.

Table 4-2
Detection Limits (MDA) for Ambient Air Sampler

Parameter	Required Minimum Detectable Activity (per individual filter) (pCi)	Approximate Sample Volume (m ³)	MDA (pCi/m ³)
Pu-239/240	0.14	48,937	4.09×10^{-6}
U-233/234	0.59	48,937	1.70×10^{-5}
U-238	0.59	48,937	1.70×10^{-5}
Am-241	0.18	48,937	5.10×10^{-6}

Notes

Based on monthly composites

There are two separate filter substrates per sample

pCi = Picocuries
 Am = Americium

m³ = Cubic meters

MDA = Minimum Detectable Activity
Pu = Plutonium

U = Uranium

4.3 Meteorological Monitoring

Continuous meteorological monitoring is conducted in the northwest Buffer Zone at a 61-m tower, instrumented at four levels (ground and 10, 25, and 61 m). Data are collected for wind speed, wind direction, temperature, relative humidity (dew point), solar radiation, precipitation, and a calculated sigma-theta (used to determine Pasquill-Gifford stability classes). Data are used as inputs for all air quality and emergency response dispersion modeling. Data are also used as inputs to CERCLA risk assessment calculations and hydrogeological assessments.

4.3.1 Data Use for Rad NESHAP

Collected meteorological data are used as Site-specific inputs to the Rad NESHAP compliance modeling. Inputs to the modeling calculations require annual average meteorological data. Continuous monitoring is required to collect representative annual values.

4.3.2 Data Use for Emergency Preparedness

Data also provide real-time input to the Site-specific emergency response model (Computer Assisted Protective Action Recommendations System [CAPARS], formerly the Terrain Responsive Atmospheric Code [TRAC]). Fifteen-minute averaged data are used to calculate the real-time movement of a pollutant plume as it disperses from the location of an accident. Five CDPHE-owned meteorological towers, as well as other nearby meteorological stations, can also provide support to Site emergency response modeling.

4.3.3 Data Use for Other Compliance Modeling

Meteorological data are basic inputs into various regulatory models used at the Site. AQM uses screening and predictive models to assess emissions impacts on the public and the environment. Exceedance of calculated thresholds may require implementation of pollution control measures and/or monitoring requirements.

4.3.4 Meteorological Monitoring Specifications

The following data quality specifications are common to all three of the above data needs. Inputs to the meteorology decisions include

Inputs

- Site-specific wind speed, wind direction, temperature, and relative humidity,

- Site-specific rainfall data,
- Atmospheric stability class calculations, and
- Solar radiation data

Boundaries

<i>Spatial</i>	Representative air flow patterns impacting the Site A minimum of 10 m above ground level
<i>Temporal</i>	Continuous data, averaged every 15 minutes Hourly averaged data, calculated from the 15-minute averages Annual averages and frequency distributions

Decision Statement

IF	Regulatory compliance, emergency response, or risk assessment modeling is performed at RFETS—
THEN	Standard, consistent, Site-specific meteorological summaries shall be used to ensure consistent model results

Monitoring Requirements

Operate meteorological monitoring station with a 95% or better data capture to provide data inputs in support of Site-required modeling programs. Operation shall follow guidance detailed in the *Site Meteorological Monitoring Plan* (DOE, 1994a)

4.4 CDPHE Air Monitoring

4.4.1 Air Pollution Control Division (APCD) Non-Radiological Ambient Air Quality Monitoring

Pollutants regulated under the CAA National Ambient Air Quality Standards (NAAQS) are monitored along the Site perimeter by the CDPHE Air Pollution Control Division (APCD). Ambient sampling for beryllium (Be) is also performed by CDPHE to verify compliance with CAQCC Regulation No. 8.

4.4.1.1 Ambient Nitrogen Dioxide (NO₂) and Particulate Monitoring

Inputs

- Ambient particulate and NO₂ concentrations, and
- Meteorological data, especially wind direction

Boundaries

Spatial Property boundaries Data characterizes concentrations as air enters the Site and leaves the Site These concentrations continually change with wind direction

Temporal Continuous NO₂ measurements No specified time increment for determining difference but averaging time for NO₂ standard is annual

Particulates Every sixth day, a 24-hour sample is collected and used to generate a quarterly estimate Averaging times for PM₁₀ standards are 24 hours and annual

Decision Statement

IF A perimeter monitor detects an exceedance of an ambient NO₂ [0.053 parts per million (ppm)] or fine particulate (PM₁₀) [50 micrograms per cubic meter (µg/m³) annual and 150 µg/m³ 24-hour] standard, and the difference in concentrations of PM₁₀ or NO₂ at upwind monitors and downwind monitors indicates that the Site may be a primary contributor to the exceedance—

THEN The Site's operating permit may be reopened and potentially revised to mitigate the exceedance

4.4.1.2 Beryllium Monitoring

Inputs

- Emission source assessment data, Air Pollutant Emission Notices (APENs), and
- Stack test data

Boundaries

Spatial Emission points (stacks) of applicable sources

Temporal 24-hour sampling average

Decision Statement

IF Be emissions from sources subject to CAQCC Regulation No 8 (40 CFR 61, Subpart C) exceed 10 grams per 24-hour period—

THEN CDPHE may take enforcement action

Inputs

- Ambient Be sampling data, and
- Meteorological data

Boundaries

Spatial Site fenceline

Temporal Samples are composited for quarterly decisions

Decision Statement

IF Ambient Be concentrations due to sources subject to CAQCC Regulation No 8 (40 CFR 61, Subpart C) exceed 0.01 $\mu\text{g}/\text{m}^3$ averaged over a 30-day period—

THEN CDPHE may take action to identify the source

4.4.2 Laboratory and Radiation Services Division (LARS) Radiological Ambient Air Quality Monitoring

CDPHE's Laboratory and Radiation Services Division (LARS) has monitored radioactive emissions from the Site since 1969. The primary purpose for this sampling has been to provide an independent assessment of public exposure to radioactive material released from the Site. LARS's monitoring program has provided validation of sampling methods used by Site organizations, confirmation of Site measurements of Pu in air, and, on occasion, helped identify errors made by Site monitoring personnel. The data are compared to Derived Concentration Guides for

nonoccupationally exposed persons. Historically, the desirability of an independent monitoring program outweighed concerns about costs, partly due to public mistrust of monitoring performed by DOE contractors.

Currently, concerns about releases during accidents or off-normal situations continue to arise and may increase as cleanup progresses. Emergency response plans for the Site include provisions for sampling environmental media after a plume dissipates. The continuous air samplers operated by LARS allow the state to begin fulfilling this obligation immediately after a release and would ultimately provide more accurate exposure assessments than output from CAPARS or other models. Routine analyses of these samples provide baseline data for comparison to known or suspected releases.

In the future, data from LARS air samplers will support APCD in its evaluation of Site compliance with NESHAP requirements, as well as providing documentation for ALARA decisions, which may arise during cleanup.

4.4.2.1 Radiological Ambient Air Quality Monitoring

Inputs

- Adequate historical and baseline data and defensible estimates of normal variation, adequate QA/QC measures on laboratory analyses. Analytes include gross alpha/gross beta on weekly samples, and Pu and Am on quarterly composites. To fully satisfy NESHAP requirements, U would have to be added to the quarterly list, should these samples be used to supplement DOE's Site measurements.

Boundaries

<i>Spatial</i>	LARS currently samples air at 12 locations: 4 east of the Industrial Area, 4 in the Buffer Zone, and 4 near the Site boundary. Total suspended particulates (TSP) are sampled at all locations. One location from each category has a collocated PM ₁₀ sampler.
<i>Temporal</i>	Individual samples are collected continuously for one week. Fractions of 13 samples are composited and analyzed as quarterly samples, corresponding to calendar quarters.

Decision Statement

IF	Any measurement of radionuclides in the air exceeds the normal variation seen in historical and baseline measurements—
THEN	A series of actions may be taken

These actions include, but are not limited to, re-analysis of composite samples for verification, analysis of individual samples included in the composite, a request for analysis of comparable samples from the nearest DOE ambient samplers, ComRad Program samplers, and/or APCD samplers, a request for investigation or explanation of elevated results from DOE or its contractor, a calculation of public dose and/or risk, and a presentation of analysis and investigation results to CDPHE management, and in public forums, as requested

IF The Student's T-test or other appropriate test to determine if the latest data point exceeds the seasonally adjusted historical range indicates exceedance of the normal range—

THEN Investigate cause, otherwise trend analysis

Limits On Decision Errors

Since Pu and Am have historically constituted a small fraction of the measured gross alpha concentration, extremely high concentrations of these nuclides would be required to result in an elevated gross alpha result. Such a sample would also be difficult to detect when composited with 12 samples in the "normal" range. Therefore, narrow limits on what is defined as the normal range and a fairly high chance of a false positive result will be necessary to identify any unplanned short-term release. In the absence of real or suspected exceedances, trend analysis should be sensitive to small, upward shifts in concentration, especially in the case of boundary samplers.

CDPHE detection limits are calculated at the 95% confidence level. While no specific detection limit is required, Table 4-3 summarizes typical detection limits for APCD and LARS samples, assuming 100% chemical recovery.

Table 4-3
Detection Limits for CDPHE Air Samples

Parameter	Approximate Sample Volume (m ³)	MDA (pCi/m ³)
APCD Pu-239/240	1,500	4 0 x 10 ⁻⁶
APCD Am-241	1,500	4 0 x 10 ⁻⁶
LARS Pu-239/240	3,400	1 0 x 10 ⁻⁶
LARS Am-241	3,400	1 0 x 10 ⁻⁶

Notes

pCi = Picocuries
 Am = Americium
 m³ = Cubic meters

MDA = Minimum Detectable Activity
 Pu = Plutonium
 U = Uranium

4.4.2.2 Precipitation Sampling

LARS collects samples of precipitation at four locations, one east of the Industrial Area, one near the 903 Pad lip area, one at the Site boundary on Indiana Street, and one at the CDPHE laboratory building in east Denver. All samples are analyzed for tritium. Those near the Industrial Area and at the Site boundary are analyzed for gross alpha/beta, Pu-239/240, and Am-241. It is recognized that the Site vicinity rarely gets enough precipitation for either atmospheric washout or deposition to have significant environmental effects, but these data are collected against the possibility that environmental modeling attains a level of sophistication where such inputs could be useful.

Inputs

- Location,
- Sample volume,
- Meteorological data, and
- Sample concentration of Am, Pu, gross alpha and gross beta

Boundaries

Spatial Sample locations are given above

Temporal All precipitation in a calendar quarter is collected and composited Results correspond to a given quarter

Decision Statement

IF Any measurement of radionuclides in precipitation exceeds the normal variation seen in historical and baseline measurements—

THEN A series of actions may be taken These include, but are not limited to, re-analysis of the samples for verification, analysis of individual ambient air filters from the same quarter, a request for analysis of comparable filters from the nearest DOE, ComRad, or APCD program samplers, a request for investigation of the results from DOE or its contractor, and a request for CDPHE and DOE modeling efforts to examine the environmental effects of such deposition

Limit on Decision Errors

All measurements are reported at the 95% confidence level It is recognized that, historically, there has been an inverse relationship between sample concentration and sample volume

4.4.2.3 Particle Size Distribution Monitoring

A cascade impactor is used to separate airborne particulate material into seven size fractions The size distribution of airborne particles is of concern because the size of the particles to which contaminants are attached is a determinant of the degree of hazard they pose, generally, smaller particles are inhaled more deeply and retained in the respiratory system for a longer period of time than larger particles Both DOE and CDPHE have conducted particle size-distribution studies The CDPHE studies are more recent and have been performed at the edge of the Industrial Area (just east of the east security fence), in the Buffer Zone, and currently at the Site perimeter on Indiana Street

Inputs

- Pu and Am concentrations, suspended particulate material concentrations, Pu/Am ratio and U-234/U-238 ratio, all by particle size, together with International Commission on Radiation Protection (ICRP) data relating to inhalation and retention of particulate material by particle size

Boundaries

- | | |
|-----------------|---|
| <i>Spatial</i> | Data collection from the E-1 (east of security fence) is complete, unless additional information is needed. Data collection from the E-2 platform (east Buffer Zone) is also complete. Data collection from E-3 platform (Indiana Street) will be completed in December 1998. Similar data from the D-13 ground level sampler (directly below the E-1 sampler) is still needed. |
| <i>Temporal</i> | Samples were collected at the E-1 platform for three years, the quantity of data is now probably sufficient to make conclusions about the variability in the particle size distribution (relative amounts in each size fraction) with respect to changes of season and the passage of time. Since the concentrations of airborne contaminants from Rocky Flats are generally lower at the E-2 and E-3 platforms, the uncertainty associated with those measurements may be too great to draw precise or reliable conclusions. |

Decision Statements

- | | |
|------|--|
| IF | Results of the size-distribution studies are well quantified and statistically valid— |
| THEN | The results will be made available for future quantitative and qualitative assessments of dose impacts from the Site |

Discussion

If there is no seasonal variation, annual variation, or variation with distance from the source in the particle size distributions, the estimates of hazards (e.g., radiation dose) from airborne particulate material will be mostly straightforward and the overall precision and certainty of conclusions will be high. If the mean particle size (or more broadly, the particle size distribution) is approximately the same as assumptions that have been made about particle size, then decisions that have been made by CDPHE in the past about the health effects of Rocky Flats and for emergency planning have been reasonably conservative, but not excessively so. Similarly, if the mean particle size (or more broadly, the particle size distribution) is approximately the same as what has been measured in the past by the Site, then reconciliation of the data sets, and the conclusions that have been drawn in the past, will be straightforward. If consensus can be gained as to the reliability and utility of the data set, the results will provide a useful tool for reconstruction of estimates of hazards from the past, for estimating the health-related impacts of remediation and other future decisions, and for emergency planning.

Limits On Decision Rule

Not necessary LARS typically calculates 95% confidence intervals on all radiometric measurements, and plans to place 95% confidence intervals on estimates drawn from the data. Other statistics will accompany the data set to allow future estimations to be made at whatever confidence level is selected. Data precision in measurements is as high as current environmental survey techniques are likely to allow.

4.5 Project-Specific Monitoring

Environmental restoration programs require air quality assessments to evaluate potential emissions from planned remedial action projects. As a result of these assessments, air quality monitoring may be performed during the project due to either risk assessment or CAA air quality screening results. Project-specific ambient monitoring may also be triggered by soil screening measurements performed for radiation worker protection.

4.5.1 Interim Measures/Interim Remedial Action (IM/IRA) Ambient Volatile Organic Compound Monitoring

The Site's remediation and deactivation operations within the Industrial Area may potentially emit significant concentrations of volatile organic compounds (VOCs). During FY95 and FY96, a VOC monitoring program was carried out along the perimeter of the Rocky Flats Industrial Area. The program's purpose was to provide data on background levels of various VOCs that had been identified as Constituents of Potential Concern or Compounds of Interest in the Final IM/IRA Decision Document for the Rocky Flats Industrial Area (DOE, 1994b). The IM/IRA Decision Document outlined a strategy to monitor VOC emissions that may occur during Site building deactivation projects. This monitoring strategy would build upon the FY95/FY96 baseline monitoring effort.

The Site-wide DQO process that took place in FY96 determined that existing point and fugitive sources of VOCs had been sufficiently characterized by this program. As a result, the VOC monitoring effort, combined with a review of future data requirements conducted during the DQO process, resulted in a decision to forego VOC verification monitoring during decontamination and decommissioning (D&D) activities. Instead, emission calculations and risk assessments will be the primary decision tools used to determine the need to implement source controls.

4.5.2 Project-Specific Ambient Radiological Monitoring

Whenever a D&D or environmental restoration project is planned that has a significant potential to release radionuclides, the existing on-Site and off-Site RAAMP network will be employed to provide project-specific monitoring. Samplers in the immediate vicinity of the project will have filters exchanged weekly instead of monthly. Filters from these "project-specific" monitors will be

screened for total alpha/beta contamination and the results compared to predefined notification levels specific to each project and each sampler. The notification levels will represent the radionuclide concentrations at each project-specific sampler that would equate to a particular off-Site dose. Notification levels will be set at the expected release rate for the project and at a level representing a 5 mrem off-Site dose (half the annual Rad NESHAP standard) if emissions continued at that level for the duration of the project.

The alpha/beta screens will allow feedback to the project personnel within a few days from when the filters are exchanged. If emissions exceed the second notification level, the sample in question will be sent to an off-Site laboratory to perform an expedited isotopic analysis. If necessary, results of the alpha/beta screening may be used by project personnel to adjust schedule or project controls to ensure Site-wide compliance with the 10 mrem standard. If warranted, sample changes can be accelerated at other RAAMP samplers or additional expedited isotopic analyses requested at any time during the project.

Inputs

- Building emissions inventory or list of potential contaminants of concern that may be disturbed/emitted by project,
- Site-specific meteorology, and
- Building or operation project plan and project schedule

Boundaries

<i>Spatial</i>	Perimeter of source being evaluated or monitored Upwind and downwind sampling locations. Two sites would be a minimum, five are typical to ensure representative sample capture relative to wind direction.
<i>Temporal</i>	Continuous sampling during periods of potential high emissions for multiple days. Continuous sampling is needed to capture sufficient sample volume for analysis.

Decision Statement

IF	Remediation projects with the potential to emit radionuclide particulates in concentrations that would exceed a notification level corresponding to half the annual Rad NESHAP standard or other Site action limits are performed—
----	--

THEN Emissions to off-Site receptors will be documented by continuous ambient monitoring

Monitoring Requirement

For Industrial Area or Buffer Zone monitoring, specific RAAMP samplers must be activated as necessary to gather representative data. The actual number of samplers and their locations must be determined based on the location and extent of the source area. The periods and frequency of sampler operation would be determined by the project activities, action levels established for the projects, and duration of remedial activities that have the potential to emit radionuclide materials.

4.6 Outstanding Issues

4.6.1 Radiological NESHAP Ambient Monitoring

Currently, the Site demonstrates compliance with the annual 10 mrem public dose standard in 40 CFR 61, Subpart H through monitoring and dispersion modeling of the effluent (monitored point) sources, and emission estimation and dispersion modeling of the non-point and unmonitored point sources, to determine the dose to the most impacted off-Site resident. The Site has historically demonstrated Rad NESHAP compliance using this approach.

As the Site continues to work toward cleanup and closure, buildings that contain significant quantities of radionuclide materials will be deactivated. Following limited contaminant removal, the ventilation systems may be sealed and turned off. In other cases, equipment removal and structural demolition will be carried out, with the existing ventilation systems disrupted or dismantled at some point in the process. In either case, a lack of directed flow from the contaminated areas will preclude normal effluent monitoring in these buildings. Such buildings will become non-point (diffuse) sources of airborne radionuclides.

Environmental restoration projects present a similar dilemma. Radionuclide emissions will occur from disturbance of contaminated soils and debris, as well as from waste treatment, handling, and packaging activities. As with building D&D, normal effluent monitoring of most such activities will not be possible.

As buildings are closed and become diffuse sources, and as the number of environmental restoration projects increases, the number of monitored effluent sources will decrease and the number of unmonitored sources at the Site will increase. In such cases where diffuse sources are primary contributors to dose, an alternative environmental monitoring approach becomes particularly appropriate for demonstrating compliance with the public dose standard of 40 CFR 61, Subpart H.

In recognition of this fact, DOE submitted a proposal to EPA and CDPHE in July 1997 describing an alternative compliance demonstration approach based on the existing 12 perimeter RAAMP samplers plus one additional sampler to be located at the northeast Site boundary. Filters would be changed at the samplers monthly and analyzed for selected Pu, U, and Am isotopes.

Under the alternative compliance demonstration method, effluent monitoring will be discontinued at insignificant point sources on Site and the ambient network will be used to demonstrate low emissions from these locations. Emissions from significant point source locations will continue to be monitored with effluent samplers. For a two-year transition period following approval of the alternative method, emissions from the Site will be modeled, including estimated diffuse source emissions, and the resulting EDE reported to allow comparison with environmental measurements. CDPHE approval was granted in September 1997. EPA approval is expected sometime in FY98.

4.6.2 Radiological NESHAP Regulatory Authority

Since regulatory primacy has not yet been transferred from EPA Region VIII to CDPHE, discussions on alternate monitoring protocols include both agencies.

4.6.3 Beryllium Effluent Stack Sampling

A review of future planned Be foundry operations may reveal a need to conduct effluent sampling for Be, such activities being subject to CDPHE Regulation No. 8. Emissions to the atmosphere are not allowed to exceed 10 grams of Be over a 24-hour period.

5 0 ECOLOGICAL MONITORING

5 1 Introduction

Ecological monitoring at Rocky Flats Environmental Technology Site (RFETS or the Site) has historically focused on characterization of the ecological components within the Buffer Zone and compliance with a variety of regulatory drivers [e g , the Endangered Species Act, the Fish and Wildlife Coordination Act, the Bald Eagle Protection Act, the Migratory Bird Treaty Act, wetlands regulations, weed control acts, the National Environmental Policy Act (NEPA), and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)] The monitoring requirements presented here were established through implementation of the data quality objective (DQO) process and represent a program that emphasizes natural resource conservation, habitat management, and regulatory compliance

Since the Ecological Monitoring Program deals with a large and dynamic natural system, where established endpoints (i e , discharge permit limitations) do not exist, a qualitative, rather than statistical, approach was adopted The program, therefore, focuses on collection of data necessary to ensure regulatory compliance and to assess the success or failure of the U S Department of Energy's (DOE's) resource conservation and habitat management efforts These conservation and management efforts are aimed at achieving a set of management goals consistent with DOE's demonstrated desire to practice ecosystem management (Congressional Research Service, 1994) and resource conservation (DOE, 1994) on its properties

These policies provide part of the basis for developing a set of environmental management goals and associated monitoring requirements that support ecological management decision making as part of the *Integrated Monitoring Plan* (IMP)

This chapter describes the technical and regulatory basis for the approach to ecological monitoring at the Site

5.2 Ecological Conservation and Management Goals and Objectives

5.2.1 Goals

In general, the goals include conservation of currently viable ecosystems, detection and management of problems or undesirable impacts to the Buffer Zone before they become severe, protection of unique and ecologically valuable natural resources in the Buffer Zone, protection of any special-concern species (threatened, endangered, candidate, proposed, state-listed, or other sensitive species), and compliance with applicable wildlife and natural resource protection regulations The goals are consistent with regulatory compliance and the DOE Buffer Zone Policy

Specific conservation and management goals for the major identified vegetation communities and one species of particular interest are presented in Table 5-1

Table 5-1
Conservation and Management Goals

Vegetation Community	Management Goal
Xeric Tallgrass Prairie	Maintain current quantity (area) and quality of the vegetation community, and maintain the current populations of bird and mammal species characteristic of xeric tallgrass prairie
Tall Upland Shrubland	Maintain current quantity (area) and quality of the vegetation community, maintain the current populations of bird and mammal species characteristic of tall upland (seep) shrubland, and maintain current population numbers and extent of Preble's meadow jumping mice within the habitat
Great Plains Riparian Woodland Complex	Maintain current quantity (area) and quality of the vegetation community, maintain the current populations of bird and mammal species characteristic of the riparian woodland complex, and maintain current population numbers and extent of Preble's meadow jumping mice within the habitat
High Quality Wetlands	Maintain current quantity (area) and quality of the vegetation community, and maintain the current populations of bird and mammal species characteristic of the largest contiguous high quality wetlands (Rock Creek and Antelope Springs/Apple Orchard Springs Wetlands Complexes)
Mesic Mixed Grassland	Maintain current contiguous extent of mesic mixed grassland for heavily and frequently used wildlife areas, and maintain the current populations of bird and mammal species characteristic of this vegetation community
Aquatic Community	Maintain current populations of aquatic organisms including invertebrate and vertebrate species characteristic of the stream and pond environment at the Site
Species of Particular Interest	
Preble's Meadow Jumping Mouse Populations	Maintain the current quantity (area) and quality of Preble's meadow jumping mouse habitat and protect all extant populations of Preble's meadow jumping mice

5.2.2 Objectives

The two primary objectives for the ecological monitoring are to determine if the Site is

- Meeting ecological conservation and management goals, and
- Complying with regulatory requirements

5.3 Descriptions of Vegetation Communities and the Preble's Meadow Jumping Mouse Populations

Vegetation communities at the Site provide specific habitats for associated wildlife, rare plants, and unusual plant associations

5.3.1 Xeric Tallgrass Prairie

The xeric mixed grassland unit selected for specific monitoring at the Site is the xeric tallgrass prairie. Identification of this vegetation community at the Site is based on the presence of big bluestem, little bluestem, prairie dropseed (*Sporobolus heterolepis*), Indian-grass (*Sorghastrum nutans*), and/or switchgrass (*Panicum virgatum*). In general, only big bluestem and little bluestem occur very commonly or abundantly at Rocky Flats. These five species are considered to be tall grass prairie relicts. When they are found in the xeric mixed grassland community with a combined cover of approximately 10% or more, the community is classified as xeric tallgrass prairie. The soil under the xeric tallgrass prairie is visibly cobbly on the surface and considered to be a sandy clay loam. This vegetation community covers the high, rocky pediment on the western one-third of the Site. The xeric tallgrass prairie vegetation community was selected at the Site for special conservation efforts due to its nationwide rarity.

The xeric needle-and-thread grass prairie, which is the other unit of xeric mixed grassland at the Site, is also considered rare, but it is not large enough to justify special management efforts. Xeric needle-and-thread grass prairie is differentiated from xeric tallgrass prairie by a greater cover of needle-and-thread grass and New Mexico feather grass (*Stipa neomexicana*), and very little cover of the big bluestem and little bluestem or other tallgrass species. Generally, the soils are not as visibly cobbly as in the xeric tallgrass prairie and have a higher visible component of caliche at the soil surface. This vegetation community occupies the tops of many of the eastern-most ridges of the Site.

5.3.2 Mesic Mixed Grassland

Mesic mixed grassland is characterized by western wheatgrass (*Agropyron smithii*) and blue grama grass (*Bouteloua gracilis*). Other common species include green needlegrass (*Stipa viridula*), Canada bluegrass (*Poa compressa*), and Kentucky bluegrass (*Poa pratensis*). The

mesic grassland has a more solid turf appearance in contrast to the bunchgrass appearance of the xeric mixed grasslands. Soils are clay loams and do not have the cobbly surficial appearance typical of xeric mixed grassland soils. Most hillsides at the Site are considered mesic mixed grassland habitat.

The quality of these grasslands varies considerably across the Site. The mesic mixed grassland on the western side of the Site has been and continues to be significantly degraded by diffuse knapweed (*Centaurea diffusa*). Mesic mixed grassland on the eastern portion of the Site has been degraded by weed species such as Japanese brome (*Bromus japonicus*), alyssum (*Alyssum minus*), and musk thistle (*Carduus nutans*) more than those on the western edge of the Site. For classification purposes, if western wheatgrass and blue grama grass form an understory beneath non-native species, then the grassland is classified as mesic mixed grassland.

Mesic mixed grasslands comprise one of the largest contiguous vegetation communities at the Site. In addition to its essential role as a foraging habitat, the size and isolation of the vegetation community often makes it very important to some wildlife species. A wide variety of grasslands birds breed and forage in this habitat. Small mammals are abundant and diverse and provide a suitable prey base for a variety of avian and mammalian predators. Many of the species supported by this vegetation community are rare or special concern.

5.3.3 High Quality Wetlands (Rock Creek and Antelope Springs/Apple Orchard Springs Complexes)

The high quality wetlands selected for monitoring and specific conservation efforts are those Site wetlands with the largest contiguous areas and the most complex plant associations. The Rock Creek wetlands are a large, seep-fed wetland complex extending approximately one mile from the foot of the eastern-most seep-fed wetlands to the western-most short marsh areas.

The Antelope Springs/Apple Orchard Wetland Complex encompasses the predominantly wet meadow, short marsh, and tall marsh habitat mosaic of upper Woman Creek Drainage Basin. These are also seep-fed wetlands that depend on groundwater discharge for their continued existence.

Predominant vegetation in these wetlands includes cattails (*Typha sp.*) and bulrush (*Scirpus sp.*) in tall marsh community, Nebraska sedge (*Carex nebraskensis*) and Baltic rush (*Juncus balticus*) in short marsh habitat, and prairie cordgrass (*Spartina pectinata*), redtop (*Agrostis stolonifera*), showy milkweed (*Asclepias speciosa*), and Missouri iris (*Iris missouriensis*) in the wet meadow habitat.

These wetlands support a variety of terrestrial and aquatic organisms. Portions of these wetlands have been designated as prime Ute Ladies'-tresses (*Spiranthes diluvialis*) habitat (a federally listed threatened plant that may occur at the Site). Other parts support sensitive amphibian species and

waterfowl. Many predatory mammals and bird species are dependent on these areas as hunting and foraging grounds due to their high prey species productivity.

5.3.4 Tall Upland Shrubland

The tall upland (seep) shrubland is comprised of stands of hawthorn (*Crataegus erythropoda*), chokecherry (*Prunus virginiana*), and occasionally wild plum (*Prunus americana*). Tall upland shrubland is found primarily on north-facing slopes above seeps, wetlands, and streams in the northern portion of the Site in the Rock Creek drainage. Small units also occur in other drainages of the Site. This vegetation community may be unique, having had no other units identified outside the general Rocky Flats vicinity, and is an important one to the resident mule deer population. Mule deer are highly reliant on tall upland shrubland for fawning cover, winter thermal cover and browse, and summer shade and isolation cover. A number of rare bird species (e.g., bluegray gnatcatchers and ashthroated flycatchers) occupy this community as well. Some units of tall upland shrubland also provide habitat for the rare Preble's meadow jumping mouse.

5.3.5 Great Plains Riparian Woodland Complex

Riparian areas are well known for the diversity of plant and animal species they support. The riparian woodland complex at the Site is a combination of two vegetation community classifications: riparian woodland and riparian shrubland. Riparian woodlands are found primarily along the drainage bottoms on Site. Due to the mosaic of trees and shrubs in the riparian areas, a contiguous mixture of both trees and shrubs is considered as the riparian woodland complex. This complex is characterized by stands of plains cottonwood (*Populus deltoides*), peach leaf willow (*Salix amygdaloides*), Siberian elm (*Ulmus pumila*), and silver poplar (*Populus albus*). Shrub species include chokecherry (*Prunus virginiana*), snowberry (*Symphoricarpos occidentalis*), coyote willow (*Salix exigua*), leadplant (*Amorpha fruticosa*), and others.

Riparian woodland complex is an important habitat for a different songbird association than the grasslands and shares some species with the tall upland shrubland. Several of the bird species that use the riparian woodland complex as foraging and nesting cover are rare species (e.g., blue grosbeaks). This vegetation community is also seasonally important to the resident mule deer herd as shelter, forage source, and fawning grounds. Large cottonwood trees imbedded within this unit provide nesting habitat for several raptor species, including great horned owls, red-tailed hawks, Swainson's hawks (a Colorado "at-risk" species), and American kestrels. Riparian woodland complex supports the greatest number of Preble's meadow jumping mice at the Site and is considered typical habitat for this species. The majority of monitoring, protection, and management of Preble's meadow jumping mouse habitat will occur in this community.

5.3.6 Aquatic Community

During 1991-1992, the Operable Unit 1 Ecological Evaluation (DOE 1992a) and the Baseline Characterization (DOE, 1992b) studies conducted sampling to characterize the aquatic community at the Site. This effort included widespread benthic invertebrate sampling across the Site, and limited fish sampling in ponds and some streams. No fish inventory has been made since then. The Colorado Wildlife Commission (CDOW) has just listed five species of small fish native to the South Platte River drainage as State endangered (the northern redbelly dace, southern redbelly dace, plains minnow, suckermouth minnow, and lake chub), and two as threatened (the brassy minnow and common shiner) (CDOW, 1998). In light of these potential listings, and the prior recommendation in the *1996 Annual Wildlife Survey Report* (Kaiser-Hill, 1997a) that fish sampling be added to the Natural Resource Compliance and Protection Program's ecological monitoring effort, Kaiser-Hill has authorized the addition of this study to the ecology program (Kaiser-Hill, 1997b). Sampling will initially focus on streams, with ponds sampled on alternate years.

The aquatic ecosystem consists of a network of ephemeral and intermittent streams across the Site, with some old stock ponds scattered across the Site. In the Walnut Creek and Woman Creek drainages, there are several water management impoundments that retain large, permanent ponds of water. Additionally, numerous seep springs feed streams at the Site and provide limited wetland habitat themselves.

While sampling of the aquatic community will attempt to quantify populations through relative abundance sampling, it should be understood that aquatic sampling in upper headwaters streams may not provide sufficient numbers to estimate stream populations. The amount of viable habitat is extremely limited due to the ephemeral nature of these streams. To attempt to sample 100% of the individuals in such habitat could result in serious damage or destruction to the habitat itself, therefore, only representative sampling of this fragile habitat will be performed.

5.3.7 Preble's Meadow Jumping Mouse Populations

Preble's meadow jumping mouse (*Zapus hudsonius preblei*) is of particular concern at the Site because it is listed as threatened by the U.S. Fish and Wildlife Service (USFWS). This listing provides special protection for the species under the Endangered Species Act.

Preble's meadow jumping mice have been recorded in all major drainages of the Site: Rock Creek, Walnut Creek, Woman Creek, and the Smart Ditch drainages. Native plant communities in these areas provide a suitable habitat for this small mammal. Jumping mice at Rocky Flats are restricted to riparian areas and pond margins, apparently requiring multi-strata vegetation with abundant herbaceous cover. Preble's meadow jumping mouse populations at the Site are frequently found in association with coyote willow. Recent studies have produced a better

understanding of population centers of the species, and studies over the past several years have also provided data to help estimate numbers of individuals within each population unit

5 4 Monitoring DQOs by Vegetation Community

DQOs were developed for monitoring in five important vegetation communities in support of the following key decision

- Given baseline information, determine whether to reevaluate current management practices to achieve specific vegetation community management goals

Results from the monitoring of these communities will facilitate the conservation and management of these resources, as well as associated wildlife, rare plants, and unusual plant associations

5.4.1 Xeric Tallgrass Prairie Vegetation Community

Inputs

- Extant area of xeric tallgrass prairie,
- Baseline estimates of plant, bird, and mammal species richness,
- Baseline estimates of bird and mammal presence or absence,
- Annual estimates of plant, bird, and mammal species richness,
- Annual weed mapping and photo surveys,
- Annual assessment of endpoints for the vegetation community and wildlife populations,
- Anticipated or estimated impact area of any proposed project,
- Identification of any plant or wildlife species populations of interest, and
- Weed control assessment monitoring, as applicable

Boundaries

Spatial Current RFETS geographic boundaries
All characteristic xeric tallgrass prairie within RFETS

Temporal Yearly decisions from 1997 forward

Decision Statement

IF One or more of the following occurs

- A measured or anticipated loss of xeric tallgrass prairie from the baseline amount,
- New weed species are reported for the vegetation communities,
- Weed mapping and/or photo surveys indicate weed species are spreading or increasing in the community,
- Weed control assessment monitoring indicates low effectiveness of a treatment option,
- A decline in the plant, bird, or mammal species richness or densities,
- Loss or major population decline of any of the predominant plant, bird, or mammal species from the vegetation community,
- Loss or major decline of any population of an identified plant species of interest or any plant or animal special-concern species, and/or
- Significant change in any of the assessment endpoints–

THEN Evaluate options to achieve the stated goals

5.4.2 Tall Upland Shrubland Community

Inputs

- Extant area of tall upland (seep) shrubland

- Baseline estimates of plant, bird, and mammal species richness
- Baseline estimates of bird and mammal presence or absence
- Annual estimates of plant, bird, and mammal species richness
- Annual weed mapping and photo surveys
- Annual assessment endpoints for the vegetation community and wildlife populations
- Anticipated or estimated impact area of any proposed project
- Identification of any plant or wildlife species populations of interest
- Weed control assessment monitoring, as applicable
- Biennial estimates of characteristic plant species area, density, height, and canopy cover within known Preble's meadow jumping mouse population areas One-half the known population areas will be monitored on each alternate year
- Baseline estimates of the known Preble's meadow jumping mouse population size estimates

Boundaries

<i>Spatial</i>	Current RFETS geographic boundaries All characteristic tall upland shrubland community within RFETS
<i>Temporal</i>	Yearly decisions from 1997 forward

Decision Statement

IF	One or more of the following occurs <ul style="list-style-type: none">• A measured or anticipated loss of tall upland shrubland vegetation community from the baseline amount,• New weed species are reported for the vegetation community,• Weed mapping and/or photo surveys indicate weed species are spreading or increasing in the vegetation community,
----	---

- Weed control assessment monitoring indicates low effectiveness of a treatment option,
- A decline in the plant, bird, or mammal species richness or densities,
- Loss or major decline of any of the predominant plant, bird, or mammal species from the vegetation community,
- Loss or major decline of any population of an identified plant species of interest or any plant or animal special-concern species,
- Significant change in any of the assessment endpoints,
- Structural measurements for any characteristic plant species (e g , area, density, height, and canopy cover) within a known Preble's meadow jumping mouse population area decreases substantially from baseline,
- The area of known Preble's meadow jumping mouse habitat within the unit decreases substantially from baseline, and/or
- Any known permanent population of Preble's meadow jumping mouse within the habitat unit decreases substantially from baseline

THEN Evaluate options to achieve the stated goals—

5.4.3 Great Plains Riparian Woodland Complex

Inputs

- Extant area of riparian woodland complex
- Baseline estimates of plant, bird, and mammal species richness
- Baseline estimates of bird and mammal presence or absence
- Annual estimates of plant, bird, and mammal species richness
- Annual weed mapping and photo surveys

- Annual assessment endpoints for the vegetation community and wildlife populations
- Anticipated or estimated impact area of any proposed project
- Identification of any plant or wildlife species populations of interest
- Weed control assessment monitoring, as applicable
- Biennial estimates of characteristic plant species area, density, height, and canopy cover within known Preble's meadow jumping mouse population areas One-half of the known population areas will be monitored in each alternate year
- Baseline estimates of the known Preble's meadow jumping mouse population size estimates

Boundaries

<i>Spatial</i>	Current RFETS geographic boundaries All characteristic Great Plains riparian woodland complex community within RFETS
<i>Temporal</i>	Yearly decisions from 1997 forward

Decision Statement

IF	One or more of the following occurs <ul style="list-style-type: none">• A measured or anticipated loss of riparian woodland complex vegetation community from the baseline amount,• New weed species are reported for the vegetation community,• Weed mapping and/or photo surveys indicate weed species are spreading or increasing in the vegetation community,• Weed control assessment monitoring indicates low effectiveness of a treatment option,• A decline in the plant, bird, or mammal species richness or densities,
----	--

- Loss or major decline of any of the predominant plant, bird, or mammal species from the vegetation community,
- Loss or major decline of any population of an identified plant species of interest or any plant or animal special-concern species,
- Significant change in any of the assessment endpoints,
- Structural measurements for any characteristic plant species (e g , area, density, height, and canopy cover) within a known Preble's meadow jumping mouse population area decrease substantially from baseline,
- The area of known Preble's meadow jumping mouse habitat within the unit decreases substantially from baseline, and/or
- Any known permanent population of Preble's meadow jumping mouse within the habitat unit decreases substantially from baseline—

THEN Evaluate options to achieve the stated goals

5.4.4 High Quality Wetlands

Inputs

- Extant wetlands based on 1994 U S Army Corps of Engineers wetland map and study (restricted to Buffer Zone only),
- Extent of wetlands will be evaluated every five years, with the next evaluation to be done in the year 2000 (to be done by U S Army Corps of Engineers),
- Baseline estimates of plant, bird, and mammal species richness,
- Baseline estimates of bird and mammal presence or absence,
- Annual estimates of plant, bird, and mammal species richness,
- Annual weed mapping and photo surveys,
- Annual assessment endpoints for the vegetation community and wildlife populations,

- Anticipated or estimated impact area of any proposed project,

- Identification of any plant or wildlife species populations of interest, and
- Weed control assessment monitoring, as applicable

Boundaries

Spatial Rock Creek and Antelope Springs/Apple Orchard Springs wetland complexes

Temporal Yearly decisions from 1997 forward

Decision Statement

IF One or more of the following occur

- Extant high quality wetlands decrease visibly from baseline,
- A measured or anticipated loss of high quality wetlands from the baseline amount,
- New weed species are reported for the vegetation community,
- Weed mapping and/or photo surveys indicate weed species are spreading or increasing in the vegetation community,
- Weed control assessment monitoring indicates low effectiveness of a treatment option,
- A decline in the plant, bird, or mammal species richness or densities,
- Loss or major decline of any of the predominant plant, bird, or mammal species from the vegetation community,
- Loss or major decline of any population of an identified plant species of interest or any plant or animal special-concern species, and/or
- Significant change in any of the assessment endpoints—

THEN Evaluate actions to achieve the stated goals

5.4 5 Mesic Mixed Grassland Vegetation Community

Inputs

- Baseline map of mesic mixed grasslands,
- Areas and positions of high and elevated use by wildlife as shown in *1995 Annual Wildlife Survey Report* (Kaiser-Hill, 1996),
- Baseline estimates of bird and mammal species richness,
- Baseline estimates of bird and mammal presence or absence,
- Annual estimates of bird and mammal species richness,
- Annual weed mapping and photo surveys,
- Anticipated or estimated impact area of any proposed project,
- Identification of any plant or wildlife species populations of interest, and
- Weed control assessment monitoring, as applicable

Boundaries

<i>Spatial</i>	Current RFETS geographic boundaries All characteristic mesic mixed grasslands within RFETS and its Buffer Zone
<i>Temporal</i>	Yearly decisions from 1997 forward regarding species richness of characteristic plants, cover of noxious weed species, and bird or mammal species numbers

Decision Statement

IF	One or more of the following occur
	<ul style="list-style-type: none"> • A measured or anticipated loss of mesic mixed grassland vegetation community from the baseline amount, • New weed species are reported for the vegetation community,

- Weed mapping and/or photo surveys indicate weed species are spreading or increasing in the vegetation community,
- Weed control assessment monitoring indicates low effectiveness of a treatment option,
- A decline in the plant, bird, or mammal species richness or densities,
- Loss or major decline of any of the predominant plant, bird, or mammal species from the vegetation community,
- Loss or major decline of any population of an identified plant species of interest, or any plant or animal special-concern species, and/or
- Significant change in any of the assessment endpoints—

THEN Evaluate actions to achieve the stated goals

5.4.6 Aquatic Community

Inputs

- Fish species present in streams in each of the major drainages at the Site,
- Fish species present in ponds in each major drainage at the Site,
- Fish species list from Baseline Characterization (1991-1992),
- Relative abundance of species (if available),
- Map of all stream drainages on the Site, and
- Locations of all sample points

Boundaries

- Streams and ponds within the Site boundaries, and
- Yearly decisions from 1999 forward

Decision Statement

- IF One of the following occurs
- A fish kill is observed,
 - A decline in fish species richness is observed, or
 - Abnormalities in fish are observed—
- THEN Evaluate actions to achieve the stated goals

5.5 Design for Integrated Ecological Monitoring

5.5.1 Decision Errors

Limits on decision errors were stated by the planning team as follows

- Reasonable expectation that monitoring will detect any change of interest listed above,
- Reasonable expectation that monitoring will not incorrectly indicate that one or more changes occurred, triggering an unnecessary evaluation of management actions,
- Reasonable expectation that monitoring will detect the presence of special-concern species and any impacts to such species, and
- Reasonable expectation that compliance with applicable regulations can be achieved

Decision errors and their consequences are presented in Table 5-2

Table 5-2
Decision Errors and Their Consequences

Decision Error	Consequences
Fail to detect one or more changes of interest that would lead to an evaluation of management actions (This error type is of greater concern)	Vegetation or aquatic community management approaches (e g , weed management, limited access, limitation of disturbances) go unchanged, with the possible loss of habitat (or species) that could otherwise be conserved or protected
Incorrectly decide one or more changes occurred, triggering an unnecessary evaluation of management actions	Unnecessary expenditure of time and money to reevaluate vegetation community management plans that are actually working

5.5.2 Statement of Need

The Site requires an Ecological Monitoring program that will provide data that can be used in management and conservation decisions during the Site cleanup over the next decade. In addition to data required for management and conservation decisions, the Site must remain in compliance with all applicable wildlife and wetland protective regulations. To meet this need, the proposed Site ecological program will monitor key variables over time in each of five vegetation communities. The data collected will be used to make discrete, but ongoing, determinations regarding changes in those key variables. These determinations will drive decisions regarding ecological protection and compliance decisions.

5.5.3 Monitoring Design

The design of the Ecological Monitoring program follows the development of decision rules regarding conservation and regulatory compliance at the Site. These decision rules specify the measurement and evaluation of analytical parameters for five vegetation communities and for Preble's meadow jumping mouse populations at the Site. They also specify the criteria that will help ensure regulatory compliance. These criteria, if detected for any of the variables, will trigger a reevaluation of ecological conservation actions or reevaluation of the Site project designs. These decision rules are formulated such that each can independently trigger an action. This is important since it will be fundamental to the way that evaluations are structured. Evaluations are structured to parallel the independence of decision rules.

The Ecological Monitoring program is designed to collect representative data from all sensitive and important vegetation communities at the Site to provide an integrated basis for decisions on vegetation community conservation and management, special-concern species protection, wetlands protection, and mitigation for all Site actions. The continuous data collection in representative vegetation communities across the entire Site allows ecologists to track trends in

wildlife and plant populations seasonally and annually. Comparisons from year to year allow ecologists to detect changes, identify potential causes, and plan corrective strategies for changes due to Site activities rather than natural fluctuations. Availability of comprehensive data for each vegetation community type at the Site greatly aids compliance and protection evaluations and decision making for specific projects, and avoids the need for many expensive, one-time-only Site-specific studies. Ecologists are able to use data from comparable vegetation community units and extrapolate those data to similar units that may not have been monitored specifically to evaluate the potential presence of plant and animal species populations. With this knowledge available, ecologists can make more cost-effective evaluations of ecological concerns and compliance and protection decisions.

The five vegetation communities to be monitored to provide the inputs discussed above were identified on the basis of data collected and analyzed from 1991 to 1995. These baseline data were evaluated to define the communities at the Site. The most important or sensitive vegetation communities were selected for conservation monitoring. Vegetation communities were described in Section 5.3.

Key parameters to be measured and used in comparisons are presented in Table 5-3 and include

- Species richness of plants in the vegetation community,
- Species richness of birds in the vegetation community,
- Species richness of mammals in the vegetation community,
- Presence of noxious weeds,
- Changes in vegetation communities,
- Species richness of fish in the aquatic community, and
- Preble's meadow jumping mouse populations and associated habitat characteristics in appropriate habitat

Table 5-3
Parameters to be Measured vs. Vegetation Community

Vegetation Community	Measure			
	Preble's Mouse Populations and Habitat Characteristics	Noxious Weeds	Changes in Vegetation Communities	Species Richness (Plant and/or Animal)
Xeric tallgrass prairie		X	X	X
Riparian woodland complex	X ^a	X	X	X
High quality wetlands		X	X	X
Tall upland shrubland	X ^a	X	X	X
Mesic mixed grassland		X	X	X
All other habitats		X	X	
Aquatic community				X

Note

^a These parameters will be measured where known Preble's meadow jumping mouse populations occur

5.5.3.1 Vegetation Communities

To summarize, there are three separate parameters that will be evaluated. These parameters are wildlife and plant species richness, presence of noxious weeds, and changes in vegetation communities.

Species richness Historically, the Site personnel have made a number of qualitative measurements of species richness. These measurements should continue. Changes in any of them, when quantified against the decision rule for species richness, should trigger further investigation, including an examination of field notes to offer potential explanations.

Baseline measurements for species richness in all vegetation communities will be determined using data gathered from the Buffer Zone in the years 1993 through 1996. Species richness surveys will be performed in all listed vegetation communities annually. Data collection will be performed in spring and summer, broken into two distinct data collection periods to ensure that spring ephemerals are recorded, as well as plants that mature late in the growing season.

Noxious Weeds Monitoring will be performed to track the success of weed control strategies. Weed species and desirable plant species cover will be characterized in a treatment area prior to treatment. After an appropriate time period for the particular treatment option used, weed species and desirable species cover will again be assessed. Management strategies for weeds, including undesirable consequences of certain treatments, can thus be tracked, and strategies can be revised based on real-time results. Weed mapping performed in 1997 will establish baselines for these measurements. This portion of the program will be a component of the integrated weed control program for the Site.

Changes in Vegetative Communities Photographic survey plots will be permanently established at vantage points adjacent to all vegetation communities to be monitored. The camera lens used for the photographs will be a standard size for all records made. Photographs will be taken from these survey points in summer and winter seasons in woody communities and annually in grasslands. Seasonal and annual comparisons of these photographs will be used to determine what type and amount of change has occurred within these vegetation communities over time. Should visible loss occur to a vegetation community, management and protection strategies will be reevaluated.

Acreage is to be calculated for each vegetation community following completion of vegetation mapping in 1996. This vegetation map will serve as the 1996 baseline map against which changes will be compared. Weed mapping and comparisons will be performed annually, or more frequently as determined by current conditions.

5.5.3.2 Preble's Meadow Jumping Mouse

Preble's meadow jumping mouse populations in selected population centers will be measured annually. Population estimates will be determined through trapping in known or potential Preble's meadow jumping mouse population areas. Trapping will occur only during the May through September activity period of this hibernator. Habitat characteristics will be monitored by measuring plant species coverage (area), density, height, and canopy cover. This will be done for each major vegetative canopy strata within the habitat. Baseline conditions will be established on the basis of all monitoring through 1996.

5.5.3.3 Mammals and Birds

The measurements to be made on birds and mammals are species richness and relative abundance. These parameters, as with plant species richness, can only be assessed annually from continuous sampling due to the seasonality of species.

Resident birds and mammals, including special-concern species, and uncommon and rare birds and mammals will be counted on line transects. The numbers counted will be determined by the dimension and number of the transects, not by the total population at large on the Site. The

number of transects will be determined based on available vegetation communities at the discretion of the ecologists on Site. Since decision rules require that an apparent change in bird and mammal species richness or presence triggers reevaluation of conservation and management actions, a minimum sampling effort will be undertaken to count representative species at the Site in any given year. Monthly surveys will attempt to record representative species expected to occur in each vegetation community for the current season. Baseline was established in the *1995 Annual Wildlife Survey Report* (Kaiser-Hill, 1996).

Bird species analysis Bird species richness will be measured monthly and assessed within each vegetation community for the seasons and the entire year.

Mammal species analysis As with bird species richness, mammal species richness will be measured monthly within each vegetation community and assessed for seasons and the entire year.

5.6 Regulatory Compliance Monitoring DQOs

In addition to ecological conservation and habitat protection, specific decisions on threatened and endangered (T&E) species, state species of special concern (SSC), and migratory birds and wetlands must be considered. The initial decision to be made is whether a proposed project has potential to impact T&E and SSC species, migratory birds, or wetlands. Such projects may require mitigation actions before they are allowed to move forward. Much of the data to support these decisions will come from the data collected from monitoring each vegetation community as discussed above. This monitoring, however, does not focus on specific areas that may be affected by the footprint of a proposed project. Therefore, additional data needs may arise to support project-specific decisions in accordance with the regulatory requirements as they occur. The discussion that follows is applicable to each of the regulatory drivers. Therefore, specific data requirements and a design for sampling and analysis are not included.

Specific management goals to be supported by these efforts are

- Protect T&E and SSC species at the Site and comply with applicable state and federal T&E species protection regulations and policies,
- Protect migratory birds at the Site and comply with applicable state and federal migratory bird protection requirements, and
- Protect Site wetlands and comply with applicable state and federal wetland protection requirements

5.6.1 Threatened, Endangered, and Special-Concern Species

Inputs

- Seasonal presence/absence, location, and abundance of T&E or SSC species in any area of potential impact by a proposed project,
- Seasonal timing of a proposed project,
- Presence of habitat considered suitable for T&E species,
- Biology of T&E or other species of concern (food habits, home range, habitat preference, nesting habits, etc), and
- Information about the anticipated impacts of the proposed project

Boundaries

<i>Spatial</i>	The area potentially affected by any Site project
<i>Temporal</i>	The time frame in which a proposed project could occur Locations of alternative project sites Jurisdictional policies and propriety

Decision Statement

IF	Any T&E or SSC species, population, individual or habitat may be affected by a proposed project—
THEN	Notify project personnel and suggest alternatives for modifying the project
IF	The project cannot be altered to achieve a “no effect” determination for the T&E species—
THEN	Advise DOE, RFFO to conduct a Section 7 consultation with the USFWS
IF	The determination is made to proceed with the proposed project by altering it—
THEN	Provide assistance to design the project to comply with regulatory requirements

The performance of biological assessments for T&E species is not within the scope of this plan, therefore, additional required methods are not discussed here

Limits on Decision Errors

The decision will be based on a qualitative study of the area of potential impact, as well as existing information about the potentially impacted area or similar habitat to that which will be affected. It should be noted that any impact to any individual is of concern, not just impact to a population. Care will be taken to identify any potential impact to T&E species.

5.6.2 Migratory Birds

Inputs

- Seasonal presence, relative abundance and location of migratory birds or their nests in areas potentially impacted by Site projects,
- Location and seasonal timing of proposed projects that might affect migratory birds, and
- Biology of potentially affected migratory bird species (food habits, home range, habitat preference, nesting habits, etc.)

Boundaries

<i>Spatial</i>	The area potentially affected by Site projects Specific areas where migratory birds or nest locations overlap the footprint of specific proposed activity (as opposed to the area potentially affected by all possible projects) Locations of alternative project sites Jurisdictional policies and propriety
<i>Temporal</i>	The time frame potentially affected by Site projects Specific time frames where migratory birds or nest locations overlap the footprint of a specific proposed activity (as opposed to the area potentially affected by all possible projects)

Decision Statement

IF	Migratory birds, their nests, fledglings, or eggs are present in a location that may be affected by a proposed project—
----	---

- | | |
|------|--|
| THEN | Notify project personnel and determine whether the project can be altered to avoid impacts |
| IF | Removal is required— |
| THEN | Obtain removal permits from the USFWS and adhere to any permit limitations |

Limits on Decision Errors

Decisions will be based on a qualitative study of the area of potential impact as well as existing information on the potentially impacted habitat. Care will be taken to identify and avoid any potential impact to migratory bird species.

5.6 3 Wetlands

Inputs

- Presence and location of wetlands on the Site (based on 1994 U S Army Corps of Engineers wetland report and field verification) (U S Army Corps of Engineers, 1994),
- Presence and location of wetlands not mapped by the U S Army Corps of Engineers,
- Determination of jurisdictional wetlands presence based on U S Army Corps of Engineers wetland delineation manual (U S Army Corps of Engineers, 1989),
- Location, timing, and description of proposed projects that potentially impact wetlands, and
- Jurisdictional policies and propriety

Boundaries

- | | |
|-----------------|--|
| <i>Spatial</i> | The area of any Site project
Specific areas where wetlands overlap the footprint of proposed activities
Locations of alternative project sites |
| <i>Temporal</i> | The time frame of any Site project |

Decision Statement

- | | |
|------|---|
| IF | Any wetland may be affected by a proposed project— |
| THEN | Advise project personnel and seek to redesign the project to avoid wetland impacts |
| IF | The project cannot be redesigned to avoid impacts— |
| THEN | Proceed with a wetland delineation in accordance with U S Army Corps of Engineers wetland delineation guidelines (U S Army Corps of Engineers, 1989) |
| IF | The delineation indicates that the wetlands is jurisdictional— |
| THEN | Advise DOE of the need to consult with the U S Army Corps of Engineers and EPA to determine the need for and amount of mitigation wetland acreage that will be required for the project |

Limits on Decision Errors

Decisions will be based on qualitative evaluation of the area of potential impact for wetlands and jurisdictional determination of wetlands present Wetlands determination will be governed by performance of a wetlands delineation in accordance with the U S Army Corps of Engineers wetlands delineation manual (U S Army Corps of Engineers, 1989) Care will be taken to identify and avoid any potential impact to wetlands The results of any wetland investigations will be conducted to err on the side of protection

6.0 SOIL MONITORING

6.1 Introduction

6.1.1 Contaminant History

Since nuclear materials were first processed at the Rocky Flats Environmental Technology Site (RFETS or the Site), the potential for dispersing contaminants into the atmosphere and onto the soils within the Industrial Area and throughout the Buffer Zone has existed due to the inherent hazards associated with handling and processing nuclear materials. Three events at the Site contributed widespread, observable radionuclide contamination of soils: the 1957 fire in Building 771, the 1969 fire in Building 776 and, most significantly, the release of contaminated cutting fluids into soils on the 903 Pad in the 1960s. The latter event culminated in the dispersion of measurable quantities of radionuclides [mostly plutonium (Pu) and americium (Am) isotopes] into the eastern Buffer Zone and off-Site areas previously identified as OU2 and OU3, respectively.

Soil "hot spots," regions of localized radionuclide contamination, are found in the Industrial Area and in some parts of the Buffer Zone. These hot spots are a result of spills, burial of contaminated drums and debris (such burial was standard operating disposal practice in the 50s and 60s), and runoff from other contaminated source areas.

Process buildings are also potential sources of contamination. However, high-efficiency particulate air (HEPA) filtration on the effluent stacks and vents of process buildings has controlled these potential emissions to the extent that this source of contamination is not considered a major contributor to surface soil contamination on and around the Site during routine operating conditions.

In addition, sediments in process-water ponds (primarily the Solar Evaporation Ponds) and surface water detention ponds (A, B, and C Series Ponds, used primarily for detention of stormwater runoff from the Industrial Area and treated sanitary waste effluent) are contaminated with radionuclides to varying degrees. These ponds hold contaminated sediments and are a potential source of contamination to subsurface soils and stream beds downstream of the ponds.

6.1.2 Existing Soil Contaminant Information

The history of spills and contaminant dispersion events at the Site is most accessible in the report commissioned by the Colorado Department of Public Health and Environment (CDPHE) entitled *Rocky Flats History - Rocky Flats Toxicologic Review and Dose Reconstruction Task 3/4 Report* (ChemRisk, 1992). Background soil contamination at the Site is primarily attributable to global fallout from atmospheric testing of nuclear weapons.

In addition, a rich database exists from which to determine the contaminant dispersion profiles at and around Rocky Flats. Surveys to determine the extent of contamination in surface soils were performed extensively in the 1970s and 1980s, and routine monitoring of surface soils was performed from 1972-1977 and 1984-1994 with limited sampling from 1978 to 1983. While such data cannot identify all areas of contamination, the results provide a good perspective on contaminants that were dispersed through larger airborne events. Limitations in survey data are related to specific hot-spots of contamination, which may exist due to burials and localized spills of contaminated materials. Many such locally contaminated areas have also been characterized during the environmental investigations of the early 90s. A discussion of soil sampling methods is discussed in *Rocky Flats Plant Final Environmental Monitoring Plan*, 1992.

The routine survey data reveal dispersed on-Site Pu 239 contaminant concentrations which range (averaging data from each location over the period of 1984 to 1994) from 11 picocuries per gram (pCi/g) down to 0.06 pCi/g (near background level) with highest concentrations found east and east-southeast of the 903 Pad. Fence-line concentrations in the surface soil range from 5 pCi/g down to 0.24 pCi/g along the Indiana Street perimeter, again with the higher concentrations to the east and east-southeast of the 903 Pad. Along the west, north and south perimeter fences, near-background concentrations are generally observed. Soil sampling results are presented in *Rocky Flats Plant Final Environmental Monitoring Plan*, 1992 (EG&G, 1992).

6.2 Site-Wide Soil Monitoring

Inherent to the issue of contaminant dispersion in the environment are several questions:

- Are the contaminants continuing to be dispersed such that the environment is being further degraded?
- Are the contaminants that are present in the environment being redistributed in some manner that is important to the environment or public health?
- What level of environmental damage has resulted?
- Is the environment recovering from the original insult?

These questions can generally be answered only on a media-specific basis, the data quality objectives (DQOs) for monitoring to determine environmental impact depend on the sensitivity of the medium being measured and the purpose of the investigation. For example, a regulatory threshold to which soil emissions contribute, such as an air dose to the public or surface water concentration, may be quite different than the threshold for measurable impact on an animal species through ingestion from plant uptake. For this reason, soil investigations have more recently been focused on project-specific potential to impact regulatory standards.

As noted earlier, a routine Site-wide soil monitoring program was conducted for many years at the Site, with sampling performed by both CDPHE and Site personnel. The 11 years of data reviewed in the *1994 Annual Site Environmental Report* (Kaiser-Hill, 1995) do not indicate any changes or trends in soil contaminant levels that would be attributable to redistribution of the contaminants over the multiple-year time-scale. Should significant releases, or other events (or project requirements) at the Site suggest a need to recharacterize the generalized distribution of contaminants, routine soil monitoring could be revisited.

6.3 Project-Specific Soil Characterization Sampling

In addition to the general characterization of contamination in the environment, the Site frequently has requirements to characterize the immediate area around project activities that will disturb potentially contaminated soils. Requirements for such project-specific sampling are generally defined at the time the project is being planned, and will follow guidelines specified in the soil disturbance permitting procedures (1-B37-HSP-12 08, Excavation and Trenching and 1-F20-ER-EMR-EM 001, Environmental Approval Process for Construction/Excavation Activities) and soil sampling procedure (4-F99-ENV-OPS-FO 20), or in other less generic project plans. Many soil samples were collected in the early 1990s to characterize the contaminant dispersion around suspected burial and spill areas. These site characterization samples were used, along with the routine data, to generate a detailed contaminant dispersion map, featuring isopleths that present the contaminant dispersion profiles around the Industrial Area. Figure 6-1 is an example of these isopleths, showing Pu concentrations in this example. As with the routine samples, the general trend is for the highest concentrations to be found near and to the east and east-southeast of the 903 Pad with isolated hotspots located near other historical release areas.

Under the *Rocky Flats Cleanup Agreement* (RFCA) (DOE et al, 1996), this kind of sampling is defined through the project Proposed Action Memorandum (PAM) or an Interim Measure/Interim Remedial Action (IM/IRA) Plan, and the Field Implementation Plan (FIP) or Sampling and Analysis Plan (SAP). The contents of such plans include results of searches of historical records, identification of sampling locations and results from pre-project surveys, and specifications for sampling of soils in the project area.

6.4 Source Identification Sampling

Under RFCA, it may become appropriate to further investigate the soils in the vicinity of a surface water exceedance point or stream in order to characterize the nature of the potential contaminant sources in that area. These investigations will have spatial extent determined primarily by assuming the probable reach of contaminants that could influence the exceedance point. These investigations will otherwise be similar to the methods used to characterize soils around some project-specific activity. Soil and sediment samples are managed under procedure 4-F99-ENV-OPS-FO 23.

Figure 6-1. Example Soil Deposition Isopleths

6.5 Outstanding Issues—Actinide Migration Study

Questions remain regarding the immediate and long-term potential for contaminated soils to disperse from the Site. These questions are being evaluated in a long-term study that is investigating actinide migration pathways and characteristics. These Actinide Migration Studies may result in the identification of additional soil data needed to facilitate the investigation. Such data needs, while not expected to result in a routine soil monitoring program, may result in short-term, more project-specific soil sampling. In the long term, the results of the study may point to long-range monitoring strategies for determining the efficacy of clean-up activities or to other parameters that must be characterized more routinely.

7.0 INTERACTIONS BETWEEN MEDIA

7.1 Overview

Some monitoring is performed to characterize interactions between the various environmental media. Possible interactions are presented in Table 7-1, which represents a conceptual model of integrated monitoring at Rocky Flats Environmental Technology Site (RFETS or the Site). Some significant interactions that require decision making and data are presented below.

Table 7-1
Interactions Between Media, Significance at RFETS,
and Monitoring to Evaluate Interactions

Interactions Between Media	Significance at RFETS	Monitoring to Evaluate Interactions
Surface Water to Ecology	Potentially significant, surface water flow and contamination could impact local ecology. However, the local ecology has remained healthy during a variety of climatic and flow conditions.	Data from existing Site-wide surface water monitoring may be used to assess potential ecological impacts. The ecological monitoring program is also designed to detect ecological changes and assess general ecological health. In addition, project-specific evaluations are conducted to assess potential impacts.
Surface Water to Groundwater	Not significant, groundwater recharge from surface water is not significant.	No monitoring is necessary to characterize or assess groundwater impacts.
Surface Water to Air	Not significant, surface water quality will not significantly impact air quality (i.e., cause exceedances of air quality standards).	Any significant impacts on air or water quality will be detected by existing DOE, CDPHE, and project-specific monitoring.
Surface Water to Soil	Potentially significant, water in drainages and ponds will not significantly increase contaminant concentrations in soil, however, runoff could spread contaminants on surface soils and increase sediment concentrations.	Soil monitoring is conducted to determine the impacts of surface water runoff and the extent of required soil removal before, during, and after individual remediation projects. Results of the actinide migration studies will be used to determine whether existing soil monitoring needs to be modified or expanded.
Groundwater to Surface Water	Significant, most of the Site groundwater flows into Site surface water drainages.	Existing surface water monitoring will detect any impacts from groundwater. Data from Site-wide groundwater monitoring (Site-wide and project-specific) is also used to assess and predict potential surface water impacts.

**Table 7-1
(continued)**

Interactions Between Media	Significance at RFETS	Monitoring to Evaluate Interactions
Groundwater to Ecology	Potentially significant, contaminated groundwater could indirectly impact ecological resources, as well as reduce groundwater flow	Data from existing Site-wide groundwater monitoring may be used to assess and predict potential ecological impacts. The ecological monitoring program is also designed to detect ecological changes.
Groundwater to Air	Not significant, groundwater will not directly affect air quality	Existing air quality monitoring will detect air quality degradation, and existing groundwater monitoring will detect groundwater contamination that could impact surface water quality.
Groundwater to Soil	Not significant, groundwater contaminants appear in surface water but are not likely to contaminate surface soils	Results of the actinide migration studies will be used to determine whether existing soil monitoring needs to be modified or expanded.
Air to Soil	Potentially significant, point source and fugitive emission sources could deposit contaminants on soil	Soil monitoring is conducted to determine the impacts of air emissions and disposition and the extent of required soil removal before, during, and after individual remediation projects. Results of the actinide migration studies will be used to determine whether existing soil monitoring needs to be modified or expanded. Also, any significant impacts on air quality will be detected by existing DOE, CDPHE, and project monitoring.
Air to Ecology	Potentially significant, point source and fugitive emissions could deposit contaminants on ecological resources	The ecological monitoring program is designed to detect ecological changes. Also, any significant impacts on air quality will be detected by existing DOE, CDPHE, and project-specific monitoring.
Air to Surface Water	Potentially significant, point source and fugitive emission sources could degrade surface water quality	Surface water monitoring (Site-wide and project-specific) will detect increases in contaminant concentrations. Also, any significant impacts on air quality will be detected by existing DOE, CDPHE, and project-specific air monitoring.

Table 7-1
(continued)

Interactions Between Media	Significance at RFETS	Monitoring to Evaluate Interactions
Air to Groundwater	Not significant, contaminants in air will not directly impact groundwater quality	Groundwater monitoring will track groundwater contamination, and air quality monitoring (Site-wide and project-specific) will detect degradation of air quality that could impact other media
Soil to Surface Water	Significant, contaminants in soils are transported to surface water via runoff and surface water quality is degraded	Site-wide and project-specific surface water monitoring will detect increases in contaminant concentrations. Soil monitoring is also conducted to determine the impacts of runoff and the extent of required soil removal before, during, and after individual remediation projects. Results of the actinide migration studies will be used to determine whether existing soil monitoring needs to be modified or expanded.
Soil to Ecology	Could be significant, contaminated soils could adversely impact local ecology	The ecological monitoring program is designed to detect ecological changes. Results of the actinide migration studies also will be used to determine whether existing soil monitoring needs to be modified or expanded.
Soil to Air	Significant, contaminants in surface soil are resuspended and air quality is affected	Any significant impacts on air quality will be detected by existing DOE, CDPHE, and project-specific monitoring. Results of the actinide migration studies also will be used to determine whether existing soil monitoring needs to be modified or expanded.
Soil to Groundwater	Significant, contaminants migrate from surface and subsurface soils to groundwater via percolation	The existing groundwater well network is designed to detect increases in contaminant concentrations in groundwater. Results of the actinide migration studies also will be used to determine whether existing soil monitoring needs to be modified or expanded.

 RFETS = Rocky Flats Environmental Technology Site

7.2 Water and Ecological Health

As indicated in Table 7-1, there are interactions between surface water, groundwater, and the flora and fauna of the Site. Concerns have been expressed that changes in flow into and out of the Site could impact significant habitat and species of concern both on Site and downstream (e.g., the Preble's meadow jumping mouse on Site, and whooping cranes in Nebraska). For example, aggregate mining activities west of the Site may alter surface water flowing onto the Site and could impact species of concern on Site and downstream. The Department of Energy, Rocky Flats Field Office (DOE, RFFO) could be held responsible for these impacts. Also, Site closure activities (e.g., closure of the Building 995 wastewater treatment plant and modification of the Interceptor Trench System) could significantly alter drainage and flow patterns. In fact, water is one of the key abiotic components structuring some of the significant habitats. Should the availability or quality of water be affected by upgradient off-Site activities or upgradient on-Site activities, significant habitats could be adversely affected.

The integrated monitoring working group, therefore, decided to collect some watershed-level information on water availability in the Buffer Zone. Current flow monitoring in the Buffer Zone is shown in Table 7-2. The data are collected at 15-minute intervals, downloaded, and compiled monthly. However, data quality objectives (DQOs) for this monitoring have not yet been developed, and data evaluation to assess ecological impacts has not yet been initiated. Site-specific relationships between water availability and ecological health are not known, therefore, it is not known what type of data are actually required. Additional data, currently uncollected, could be required (e.g., accurate information on purchased water, data on exfiltration and infiltration of underground pipes, and data on alluvial flow through the Buffer Zone habitats of concern).

The following preliminary decision rules have been proposed:

Preliminary Secondary Data Uses Could Include

- Determining the impact of mining on Rock Creek water quality and availability,
- Interpreting potential causes of declines in any of the valued habitats on Site,
- Supporting water management planning and Water Right issues,
- Evaluating cumulative impacts of all actions (on and off Site),
- Validating any predicted impacts of a selected alternative on downstream resources, and
- Supporting Site biological assessments and U.S. Fish and Wildlife Service (USFWS) biological opinions.

Table 7-2
Buffer Zone Flow Monitoring Stations

Station Identifiers	Locations	Monitoring in Addition to Flow
GS01	Woman Creek/Indiana Street	RFCA and possible nutrient load monitoring, precipitation

GS03	Walnut Creek/Indiana Street	RFCA and possible nutrient load monitoring, precipitation
GS04	Rock Creek at Highway 128	Precipitation
GS05	North Woman Creek at west boundary	Precipitation
GS06	South Woman Creek at west boundary	--
SW134	Rock Creek at west boundary (Gravel Pit)	(4 samples per year quarterly)
GS16	Antelope Springs	
SW118	Above Portal 3, north side of road	RFCA Source Location

Notes

IA	=	Industrial Area
IM/IRA	=	Interim Measures/Interim Remedial Action
NPDES	=	National Pollutant Discharge Elimination System
RFCA	=	<i>Rocky Flats Cleanup Agreement</i> (DOE et al , 1996)
RMRS	=	Rocky Mountain Remediation Services, L L C
SID	=	South Interceptor Ditch

Inputs

- Drainage flow,
- Water level measurements, and
- Stream gain or loss

Preliminary Boundaries Include

<i>Spatial</i>	All surface waters entering and leaving the Site in the Rock Creek, Walnut, and Woman Creek drainages
<i>Temporal</i>	Seasonal and yearly determinations of total water availability and basic water quality

Preliminary Decision Statement

IF	The seasonal average or yearly average water availability or quality entering Rock Creek, Walnut Creek, or Women Creek drainages diminishes below baseline due to off-Site activities—
THEN	The Site will notify Jefferson County and the USFWS to determine what actions, if any, should be taken to restore availability and/or quality to historical levels
IF	Activities occurring within Site boundaries result in a depletion of the seasonal or yearly average natural flow greater than the historic baseline, or at rates that are determined to have a negative impact on downstream habitats or individual species—
THEN	The Site will determine what management actions should be taken to ameliorate this problem
IF	Significant changes to alluvial groundwater availability in a wetlands habitat are determined—
THEN	Notify parties of potential impacts to the wetlands habitat and continue groundwater and ecological monitoring
IF	A proposed action could adversely affect a listed species or its critical habitat—
THEN	The Site will enter into formal consultation with the USFWS

Preliminary Acceptable Decision Errors Include

- Confidence that Significant Events are Physically Sampled and Representative
 - Flow will be continually monitored, seasonal composite samples will be taken to evaluate basic water chemistry. An effort will be made to gather a sample representative of conditions during the season.
- Acceptable Decision Error Rates for Statistical Sampling Design
 - The function of this monitoring is to provide a watershed-level measure of water availability and quality to serve as an early warning that habitats reliant on these waters may be adversely impacted if changes continue. The Site is more concerned with failing to detect a decrease in water availability or quality over historical levels than mistakenly determining that a decrease has occurred. The precise change over time that is of concern has not been established because the water requirements of the habitats are not fully understood. Therefore, no attempt has been made to establish quantitative limits on decision errors or to generate a statistical design.
 - The integrated monitoring working group will continue to address water and ecology monitoring integration. The group needs to determine how to effectively use the Buffer Zone flow data or eliminate that monitoring altogether. The group also needs to determine if it would be cost-effective to collect additional data and how those data could be used to assess impacts on ecological health.
